YOUNG, ERNEST BOYEN, M.D.
YOUNG, L. M., M.D.

- Morrow, Prince A.** Sanitary and moral prophylaxis, 674.
- Mosher, Harris Peyton.** Inflammation of the frontal sinus, 645.
- Mumford, James G.** John Hunter. 1728 to 1793, 201.
- Nichols, Edward H., and Smith, Homer B.** The physical aspect of American football, 1.
- Nichols, John H.** What special instructions regarding tuberculosis should be given institution nurses and other employees? Are nurses caring for cases of tuberculosis in danger of contracting the disease? 64.
- Northrup, W. P.** Cold fresh air treatment of pneumonia. A case, 216.
- Otis, Edward O.** The methods and aims of the physician, 391.
- Pearson, R. A.** Some influences in favor of better market milk, 463.
- Preyer, Frederick B.** The homeopathic principle, 336.
- Price, Austin T.** The suppression of tuberculosis in our daily breads, 67.
- Prütz, Franz.** The use and abuse of digitalis, 551.
- Potter, Nathaniel Bowditch.** The value of Virchow's smooth atrophy of the base of the tongue in the diagnosis of syphilis, 260.
- Pratt, Joseph H.** On the development of scientific hydrotherapy, 85; progress in pathology, 318, 343; the "home sanatorium" treatment of consumption, 210.
- Prince, Morton.** Head injuries, 182.
- Quackenbush, Alex.** Amautic family idiocy: a report of four cases, 18.
- Quinby, Charles E.** The treatment of organic heart disease by the pneumatic cabinet, 543.
- Richardson, Mark W.** Progress in thoracic diseases, 296.
- Richardson, Oscar, and Davis, Lincoln.** A case of congenital occlusion of the small intestine. Operation, 206.
- Robinson, Beverly.** Some truths and some fictions, 691; "the purification of therapeutics," 281.
- Rockwell, A. E. P.** The testimony of the fathers, 622.
- Rogers, Albert E.** The successful treatment of tuberculosis, 291.
- Rogers, O. F.** Should the tuberculosis insane in hospitals be segregated? 62.
- Rosano, W. D., and Southard, E. E.** Cerebral seizures with suboccipital pain: military cerebral and gross vertebral aneurysms, 312.
- Rosch, D. B. N. John.** A correction, 537.
- Sachs, B.** Serious head injuries and the indications for operative treatment, 176.
- Sanford, Henry L., Allen, Dudley P., and Dolley, D. H.** Traumatic defects of the skull. Their relation to epilepsy. A clinical and experimental study of their repair, 396.
- Sawmell, David D.** General suppurative peritonitis without obvious cause, 341; general purulent peritonitis without obvious cause; secondary enterostomy, 340.
- Scudder, Charles L.** A metastatic hypernephroma, 271; cerebral embolism following ligation of the external carotid artery, 317; stenosis of the pylorus in infancy. The report of a second case successfully operated upon. Remarks, 208.
- Seimmes, R. O.** "The medical profession and the medical journals in relation to nostrums," 331.
- Shattuck, Frederick G.** A case of hypernephroma, 270; depletion in heart disease, 549; method of instruction in the Harvard Medical School, 602; the value of drugs in therapeutics, 333; how progress comes in medicine, 602.
- Shattuck, George B.** Exostoses, 343; gout, 342.
- Smith, Homer B., and Nichols, Edward H.** The physical aspect of American football, 1.
- Smith, Theodore A.** What is the relation between human and bovine tuberculosis and how does it affect inmates of public institutions? 60.
- Southard, E. E., and Ruston, W. D.** Cerebral seizures and suboccipital pain: military cerebral and gross vertebral aneurysms, 312.
- Soutter, Robert R.** Shoes and feet, 40.
- Spencer, Edmund D.** Photophobia. A nasal reflex, 236.
- Stevens, E. H.** Puerperal septicemia, 12.
- Storer, Malcolm.** Bilateral torsion of the Fallopian tubes, 285.
- Strong, Lawrence W.** Immunity against tuberculosis, 140.
- Swett, John B.** A case of extra-uterine pregnancy, 158.
- Sylvester, Charles P.** A case of psoriasis cured by laparotomy and cauterization, 583.
- Taylor, E. W., and Luce, D. S.** A case of adiposis dolorosa, 187.
- Thornidge, Paul, and Watson, F. S.** Progress in genito-urinary surgery, 230.
- Tilston, Wilder.** The treatment of tuberculosis in public institutions, 66.
- Towle, Harvey P., and Bowen, John T.** Report on progress in dermatology, 584.
- Townsend, David.** Day sanatorium for consumptives, Parker Hill, Boston, 602.
- Tracy, Edward A.** Open-air treatment of bone tuberculosis, 169.
- Walton, G. L.** Crush of cord from spinal fracture, 632.
- Walton, G. L., and Brewster, G. W. W.** Fracture of skull probably involving the base. Recovery after operation. Analysis of the aphasia, 610.
- Watson, F. S.** Prostatic hypertrophy, perineal prostatectomy. Recovery. Immediate result cure, 340; pyopneumo-thorax. Operation, 340.
- Watson, F. S., and Thornidge, Paul.** Progress in genito-urinary surgery, 230.
- Weiser, Walter R.** Gunshot wounds of the head and spine, 314.
- Wellman, F. C.** Some etiological suggestions. (1) Concerning the significance of an embryo-intestinal worm found in the blood stream; (2) regarding a sporotricha found in yaws papules; and (3) a hint as to the possible connection between chiggers and anidum, 485; supplementary note on a sporotricha found in yaws papules, 490.
- Wesselhoef, Walter.** A system of clinical research directed purely towards therapeutics, 479.
- Wheatley, Frank G.** Ready-made remedies, 235.
- White, James C.** The past of the Boston Medical Association. Changes in the fee-table, 512.
- Williams, Francis H.** A further note on a new method of using the Roentgen rays in the consideration of primary treatment of some early cases of breast cancer by these rays, 641.
- Wolbach, S. B., and Locke, Edwin A.** A case of multiple ulcers of the gall bladder, 666.
- Wright, James Homer.** The origin and nature of the blood plates, 643.
- Young, Ernest Boyen.** An inexpensive mechanical treatment for anterior metatarsalgia, 338; fibroids and pregnancy, extra- and intra-uterine pregnancy, 339.
- Young, L. M.** Franklin's contributions to medicine, 597.

SUBJECTS.

- Abdomen.** Contusions of the abdomen, Hubbard, Joshua C., 100.
- Abscess.** Brain abscess. Operation. Recovery, Hammond, Philip, 102.
- Addresses.** 1846-1906. The Boston Medical Association, Cheever, David W., 502; the value of laboratory methods to the country practitioner, Cowan, R. B., 257; the problem of psychiatry in the functional psychoses, Cowles, Edward, 117, 142, 171; medical statistics and the sanitary department of the Russian forces in the Far East, Hoff, John Van K., 599; the physician's duty to his fellow-practitioner and to himself, Lindley, Walter, 481; the medical profession and the issues which confront it, Mayo, William J., 607; John Hunter, 1728 to 1793, Mumford, James G., 201; the methods and aims of the physician, Otis, Edward O., 391; the nature and progress of malignant disease, Bryant, Joseph D., 723; how progress comes in medicine, Shattuck, Frederick G., 602.
- Adiposis Dolorosa.** A case of adiposis dolorosa, Taylor, E. W., and Luce, D. S., 187.
- American Medical Association.** The Boston session of the American Medical Association, 281; the House of Delegates, American Medical Association, Gray, George W., 721.
- American Medicine.** *American Medicine* becomes a monthly, 389.
- Amputation.** A case of amputation at the shoulder joint for infection with Welch's gas-producing bacillus. Recovery, Colman, E. A., 270.
- Aneurysms.** Cerebral seizures with suboccipital pain: military cerebral and gross vertebral aneurysms, Ruston, W. D., and Southard, E. E., 312.
- Appendix.** Appendix, Böhm, Max, 629.
- Army.** An army field hospital at Boston during the A. M. A. meeting, 421; army medical corps examinations, 229.
- Arsenic.** Arsenic in wines, 421.
- Auto-Intoxication.** A consideration of the treatment of auto-intoxication and auto-infection where they are the cause of mental disturbance, Briggs, L. Vernon, 431; 494; 493.
- Blood Plates.** The origin and nature of the blood plates, Wright, James Homer, 643.
- Blood Pressure.** Human blood pressure and pulse as affected by altitude, 307.
- Books Reviewed.** Arnell, James R., Arnell's epitome of clinical diagnosis and analysis, 21; Autenrieth, Wilhelm, the detection of poisons and strong drugs, 500; Bartley, Elias H., a textbook of medical and pharmaceutical chemistry, 251; Blackiston, P. S. and Co., the physician's visiting list for 1909/1910, Boston, L. Napoleon, a textbook of clinical diagnosis by laboratory methods, 110; Brun, Max, the animal parasites of man, 215; Brubaker, Albert P., a textbook of human physiology, 592; Bruce, J. Mitchell, materia medica and therapeutics, 560; Butler, Glenworth Reeve, the diagnostics of internal medicine. A clinical treatise upon the recognized principles of medical diagnosis, 78; Cabot, Richard C., case teaching in medicine, 626; Callie, Augustus, differential diagnosis and treatment of disease, 715; Caldwell, Robert, military hygiene, 503; Church, Archibald, and Peterson, Frederick, nervous and mental diseases, 225; Coleman, Warren, a syllabus of materia medica, 353; Cotton, Alfred Cleveland, the medical diseases of infancy and childhood, 598; Cuthbert, David M., Keio Cuthbert's materia medica, 280; Cushman, Arthur R., a textbook of pharmacology and therapeutics or action of drugs in health and disease, 584; Davis, A. Edward, and Douglass, Beaman, eye, ear, nose and throat nursing, 685; Douglass, Beaman, nose and throat surgery. A nasal sinus surgery with operations on the nose and throat, 686; Edwards, Charles W., and Cushman, Arthur R., laboratory guide in experimental pharmacology, 161; Fowler, Nathaniel C., Jr., gumption: the progressions of Newson New, 160; Friihwald, Ferdinand, a reference handbook of the diseases of children, 501; Furac, J. Rognes de, manual of psychiatry, 222; Gray, Henry, anatomy, descriptive and surgical, 507; Croft, John E., materia medica for nurses, 560; Hanke, Victor, the treatment of diseases of the eye, 744; Harbaugh, C. H., a doctor's manual. For the settlement of accident and health claims, 710; Hare, Hobart Amory, and others, the national standard dispensatory, 212; Harrington, Thomas Francis, the Harvard Medical School. A history, narrative and documentary, 1782-1902; 22; Harvard Medical School, outlines of medical diagnosis, 50; Heinemann, Paul G., a laboratory guide in bacteriology, 626; Heintzmann, Louis, clinical analysis and diagnosis, 353; Hirst, Barton Cooke, a textbook of disease of women, 22; Holt, L. Emmett, the diseases of infancy and childhood, 444; Howard, Russell, surgical nursing and principles of surgery for nurses, 744; Howell, W. H., a textbook of physiology for medical students and physicians, 741; Hunter, Robert, poverty, 416; Jackson George Thomas, ready reference handbook of diseases of the skin, 160; Hutchinson, Robert, and Raimy, Harry, clinical methods, 530; Javal, Emile, on becoming blind. Advice for the use of persons losing their sight, 443; Kilner, Theron Wendell, the physical examination of infants and children, 509; King, William Harvey, static, high frequency, radium and radium therapy, 275; Klopstock, L. and Kowarsky, A., a manual of clinical chemistry, microscopy and bacteriology, 50; Koplik, Henry. Koplik on diseases of children, 354; Kraepelin, Emil, lectures on clinical psychiatry, 251; Kraft-Ebing, R. von,

- [illegible]

crush of cord from spinal fracture, Walton, G. L., 632; fracture of skull probably involving the base. Recovery after operation. Analysis of the aphasia, Walton, G. L., and Brewster, G. W., 630.
Fraudulent Practitioners. Prosecution of fraudulent practitioners, 82.

Gall Bladder. A case of multiple ulcers of the gall bladder, Locke, Edwin A., and Wolbach, S. B., 606.
Gout. Gout, Shattuck, George B., 342.

Gynecology. A case of acute torsion of the Fallopian tube with hemato-salpinx, Burrage, W. L., 293; recent progress in gynecology, Burrage, W. L., 438; adomyoma of the uterus. A report of four cases, Graves, W. P., 283; vaginoplexy, Graves, W. P., 152; a review of five cases of ovarian cyst with twisted pedicle, Green, Charles M., 293; case of inverted uterus, Hare, C. H., 157; bilateral torsion of the Fallopian tubes, Storer, Malcolm, 285.

Harvard Medical School. Charles E. Buckingham, M.D., "Errors in the Harvard Medical School History," Buckingham, Edward M., 169; "Errors in the Harvard Medical School History," Harrington, Thomas F., 141; method of instruction in the Harvard Medical School, Shattuck, Frederick C., 607; the Harvard Medical School as viewed at St. Paul, 450.

Head Injuries. Brain injuries. 1. Gunshot wound involving both occipital lobes: study of visual field. 2. Fracture of skull: injury to frontal lobe, Baldwin, Henry C., 183; indications for operation in head injuries, Bullard, William N., 184; head injuries, Prince, Morton, 182; serious head injuries and the indications for operative treatment, Sachs, B., 176; gunshot wounds of the head and spine, Weiser, Walter K., 314.
Health. Dyeing health statistics, Myers, Thomas J., 42.

Heart Disease. Acute following adherent pericarditis and peripneumonitis, Cutler, E. G., 620; the treatment of chronic diseases of the heart by the Nauehm methods: its indications and contra-indications, Kinnicut, Francis T., 539; the use and abuse of digitalis, Pfaff, Frank, 531; the treatment of organic heart disease by the pneumatic cabinet, Quimby, Charles E., 543; depletion in heart disease, Shattuck, Frederick C., 540.

Hematology. The teaching of hematology, Larrabee, Ralph C., 577.
Homeopathy. Homeopathy and the Massachusetts Medical Society, Claver, David W., 431; the homeopathic practitioner, Perry, Frederick B., 336; testimony of the fathers, Rockwell, A. E., 522; a system of clinical research directed purely towards therapeutic ends, Wessel-hoff, Walter, 479.

Hospital Conference. The hospital conference of the city of New York, 431.
Hospital Organization. Committee on hospital organization in New York, 199.

Hydrotherapy. On the development of scientific hydrotherapy, Pratt, Joseph H., 81.

Hygiene. The sanitary importance of clean milk, Harrington, Charles, 121; some influences in favor of better market milk, Pearson, R. A., 463.
Hyperemia. The hyperemia treatment of congested and inflamed tissues, Bradford, E. H., 671.

Idiocy. Amaurotic family form: a report of four cases, Quackenbush, Alex., 238.

Intestine. A case of congenital occlusion of the small intestine. Operation. Autopsy, Davis, Lincoln, and Richardson, Oscar, 266.

Joint Disease. The treatment of joint disease by passive congestion, Harriwell, H. F., 483; remarks on the infections of joints, Lovett, Robert W., 575.

Laboratory Methods. The value of laboratory methods to the country practitioner, Cowan, J. R., 257.

Landry's Paralysis. A case of Landry's paralysis, Alsever, W. D., 408.

Lateral Curvature. A contribution to the etiology of "lateral curvature" of the spine, Böhm, Max, 99; recent researches on the pathology and etiology of juvenile spine deformities. (Lateral curvature of the spine.) Böhm, Max, 624.

Lympho-Sarcoma. General lympho-sarcoma especially active in the throat. Preliminary report, Emerson, F. P., 104.

Malaria. Analysis of the one hundred and twenty cases of malaria occurring at Camp Gregg, Philippine Islands, Chamberlain, Weston P., 29; malaria in the tropics, 451.

Medical Notes. 251; 531; 80; 112; 137; 164; 196; 226; 251; 279; 304; 328; 357; 380; 410; 447; 476; 505; 533; 563; 592; 630; 661; 688; 718; 747.

Medicine. A definition of the practice of medicine, 199; the border line in medicine and surgery, 329; Franklin's contributions to medicine, Young, L. M., 597.

Memorial. Joseph Leidy memorial, 359; a memorial to the late Dr. Chas. C. Chaddock at the Medical Library Congress, 255; resolutions on the death of

Meningitis. A case of acute meningitis. Operation. Recovery, Crockett, E. A., 103; epidemic cerebrospinal meningitis: clinical report and analysis of special symptoms in typical cases, with remarks on the treatment, 280; lectures on pneumonia and cerebrospinal meningitis, 26.

Mental Disease. Observation hospital for mental disease. Some reasons why there should be one in Boston, or at least an observation ward; statistics of those at Albany and Glasgow, Briggs, L. Vernon, 606.

Metatarsalgia. An inexpensive mechanical treatment for anterior metatarsalgia, Young, Ernest Boyen, 338.

Miscellaneous. Lectures on pneumonia and cerebrospinal meningitis, 26; immunization of cows against tuberculosis, 27; prosecution of fraudulent practitioners, 82; the Cartwright lectures, 1908, 83; testimonial to Mr. Henry H. Sprague, 114; import of drugs and proprietary medicines, a report, a unique case, 140; the State Board of Charity on Dr. Bowditch's dismissal, 140; a tribute to Prof. E. S. Wood, 167; some obstetrical methods practised in the Philippines, 167; the Arctic climate, 167; International Laryngo-Rhinology Congress, 168; a definition of the practice of medicine, 199; committee on hospital organization in New York, 199; the edibility of animal species, 199; the Fifteenth International Medical Congress, 228; a review of yellow fever epidemics in Maryland, 229; army medical corps examinations, 229; Professor Minot concerning old age, 254; International Medical Congress, 255; epidemic cerebrospinal meningitis: clinical report and analysis of special symptoms in typical cases, with remarks on

the treatment, 280; the Boston session of the American Medical Association, 281; official organ of the National Association for the Study and Prevention of Tuberculosis, 281; human blood, pressure and pulse as affected by altitude, 307; the New Haven Medical Association, 307; the border line in medicine and surgery, 329; general paralysis among women, 359; Joseph Leidy memorial, 359; a memorial to the late Dr. Chaddock at the Medical Library, 359; *American Medicine* becomes a monthly, 380; arsenic in wines, 421; an army field hospital in Boston during the A. M. A. meeting, 421; the Harvard Medical School as viewed at St. Paul, 450; malaria in the tropics, 451; the hospital conference of the city of New York, 451; the International Congress at Lisbon, 478; a monthly, 478; the statistics of the medical students in Germany, 507; in honor of Dr. J. W. C. Ely's sixty years of active practice, 534; opening exercises by the King and Queen of Portugal, of the International Medical Congress at Lisbon, April 19, 1906, 536; letters from San Francisco, 536; centennial of the Boston Medical Association, 537; opening exercises of laboratories of the Rockefeller Institute for Medical Research, 537; the labelling of drugs and foods, 591; a guide book for physicians visiting Boston, 597; governmental meat inspection, 604; national voluntary emergency-service medical corps, 665; British Medical Association, 665; the International Medical Congress, 690; councillors' meeting, 720; criminal anthropology and thug skulls, 749.
Moral Prophylaxis. Sanitary and moral prophylaxis, Morrow, France A., 674.

National Association. Official organ of the National Association for the Study and Prevention of Tuberculosis, 281.

Nauehm Methods. The treatment of chronic diseases of the heart by the Nauehm methods: its indications and contra-indications, Kinnicut, Francis T., 539.

Needle Holder. New needle holder, Barney, J. Dellinger, 375.

New Haven. The New Haven Medical Association, 307.

New Instruments. A new needle holder, Barney, J. Dellinger, 375; new instrument. Tonsil scissors, Blodgett, John H., 237; a new gouge for subcutaneous excision of the nose, Coffin, Robert, 217; apparatus for local application of dry cold and heat, Baird, Addison W., 298.
Nostrums. The medical profession and the medical journals in relation to nostrums, Billings, Frank, 234; "the medical profession and the medical journals in relation to nostrums," Semmes, R. O., 331; ready-made remedies, Wheatley, Frank G., 735.

Obituary. Prof. Alfred Schaper, 55; Emmet Cooper Dent, M.D., 82; James Arthur Mahon, M.D., 114; Ernst Ziegler, M.D., 166; George Ryerson Fowler, M.D., 198; John Slade Ely, M.D., 198; Charles A. THE PHYSICAL ASPECT OF AMERICAN FOOTBALL.

BY EDWARD H. STEWART, A.M., M.D.,

Assistant Visiting Surgeon, the Boston City Hospital, Assistant Professor of Surgical Pathology, Harvard Medical School,

AND

HOMER B. SMITH, M.D.,

Recently House Surgeon at the Boston City Hospital.

THE following is a report of the experience of the writers in the care of the football squad of Harvard University during the season extending from Sept. 12 to Nov. 25, 1905.

The report is presented, first, in order to show the number, character and severity of the injuries which were received, while playing football, by the members of the football squad of one university. The first table of figures includes all injuries received by the players previous to this season, while playing football either at school or in college; the second table includes all injuries received this year. Second, to illustrate general methods which were found to be useful in the treatment of acute traumatism common among football players; and, finally, to present certain special methods of treatment of special injuries.

The report is based upon (1) the written statements of the players themselves regarding the injuries they had received while playing football previous to this year. Every man was required, on joining the squad, to make out a card for a card catalogue, on which he stated the number and the character of his previous injuries. (2) Clinical records which were kept by the writers of the cases which came under their observation and treatment. These records were kept only in case of injuries of great or moderate severity, practically all of which were sufficient to keep men out of the play for a greater or less length of time. No clinical record was kept, however, of the infinity of minor injuries which constantly came under observation, such as abrasions, scratches, minor contusions. (3) The answers received to a circular letter which was sent, after the close of the season, to every one who had been at any time a member of the squad. This circular letter asked the number and character of previous injuries, the length of time they were kept out of the play by those injuries and the length of time they were kept away from college duties, and whether recovery from those injuries was now complete. Similar questions also were asked in regard to injuries received during the season of 1905. A hundred and fifty such circular letters were sent out and answers were received from one hundred and ten men.

Besides the members of the university squad, players from the freshmen and class squads also were treated, but no clinical record was kept of those cases, nor are they included in the statistics presented in this paper, although a considerable number of serious injuries was treated among members of those squads.

There were 150 men altogether in the football squad, of whom 50, at least, played but a very

short time, varying from a few days to a week or two. Of the remaining 100, only 70 can be said to represent the real playing strength of the football squad. This fact makes the proportion of injuries received this year almost double as great as would appear at first sight.

It has been claimed that the number of injuries received this year was unusually great and more numerous than in any preceding season. In the absence of any available records of other seasons this point cannot be determined accurately, but in our opinion it is probable that this season is not markedly worse than preceding ones. We are confirmed in this opinion by interviews with other men who previously have had medical charge of the football squad. One or the other of us was constantly present at the field, from half past three or earlier until dark. The men were very carefully observed and many injuries were recognized which would have escaped less close observation. In comparing the figures in this paper with those of other institutions where no constant surgical attendance is maintained, the numbers may appear relatively large because, in the absence of such observation, many injuries would escape notice.

The players of the university squad were required by the head coach to report every injury, no matter how trivial it seemed to them, to the surgeon in charge. In expectation of numerous minor injuries and with a knowledge of the occurrence, in some previous years, of occasional epidemics of minor infections, special precautions were taken regarding asepsis this year. In the first place, an efficient sterilizing outfit was installed. A sufficient supply of clean towels was provided in order to prevent the possibility of transmission of skin infections, and pains were taken to see that the underclothing of the players was changed frequently. As a result of these precautions there was no case of an infected wound during the season nor did any case of skin infection occur. This result, we believe, has not been paralleled in former years.

Believing that a first-class man slightly injured was inferior to a second-rate man in first-class physical condition, great pains were exercised to prevent injured men from returning to the play too soon. This apparently excessive caution of the surgeons met in some cases with better opposition from the players. In fact, one man, at least, stated that if it were not for the presence of a surgeon, he would be playing. The wisdom of caution, however, was shown by the fact that in but two cases were men allowed to play as soon as to have an immediate recurrence of their previous disability. On the other hand, it must be stated that the position of the surgeon is rather a trying one. Football players are quite unlike ordinary private patients. Their disregard for pain is marked and their great desire to be sufficiently recovered from an injury to be able to play, in spite of what was considered by the players to be excessive caution on the part of the "chances" were taken. For instance, a treatment, under ordinary circumstances, with a dis-

located semilunar cartilage, would be perfectly contented to lead a more or less quiet life for a considerable length of time. The football player, however, as soon as the acute symptoms have disappeared, is quite unwilling to be prevented from playing. In no case was any sedative drug used in order to deaden the pain of an injury so as to allow a player to take part in a game before recovery was complete.

The injuries were received in various ways: some in open play, some in the mechanical drill of "tackling the dummy," but a very great proportion occurred in the "bunch" or "pile" which forms after a player running the ball is tackled. The surgeons very quickly got in the way of watching every pile with great interest and apprehension. The exact proportion between the injuries received in the open and in the pile, however, are not controlled by accurate figures. The number of injuries received in the games and in practice were proportionately about the same.

LIST OF INJURIES RECEIVED WHILE PLAYING FOOTBALL PRIOR TO 1905.

| | |
|--|-----|
| Sprain of thumb | 9 |
| Bruise of knee | 1 |
| Cuts, various places, usually head | 5 |
| Bruised shoulder ¹ | 31 |
| Dislocation of elbow | 1 |
| Injury to back | 2 |
| Synovitis of knee | 39 |
| Sprain of ankle | 12 |
| Concussion ² | 7 |
| Fractured wrist | 2 |
| Dislocation of knee | 1 |
| Fractured rib ³ | 4 |
| Dislocation of shoulder | 3 |
| Contusion of chest | 1 |
| Fractured clavicle | 7 |
| Ruptured muscle | 7 |
| Fractured arm | 4 |
| Injury to eye | 1 |
| Sprain of wrist | 3 |
| Ruptured internal lateral ligament of knee | 1 |
| Dislocation of thumb | 1 |
| Fractured toe | 1 |
| Broken nose | 16 |
| Fractured olecranon | 1 |
| Dislocation of ankle | 1 |
| Broken foot | 1 |
| Sprained toe | 1 |
| Fractured ankle | 2 |
| Fractured carpus | 3 |
| Fractured elbow | 2 |
| Dislocation of outer end clavicle | 5 |
| Fractured finger | 8 |
| Injury to kidney ⁴ | 1 |
| Fractured fibula | 1 |
| Teeth out | 1 |
| Total | 216 |

LIST OF INJURIES RECEIVED DURING 1905.

| | |
|---------------------------|----|
| Sprained thumb | 1 |
| Fractured fibula | 1 |
| Cuts (requiring stitches) | 12 |
| Bruises ⁵ | 6 |

¹ Judging from our own experience, a very considerable number of the so-called bruised shoulders must have been partial dislocations of the outer end of the collar bone.

² Judging from this year's experience and from conversations with the players, we believe that the figure under concussion is much too small.

³ The same statement applies to fractured ribs.

⁴ The nature of the injury to the kidney was not specified.

⁵ These bruises were sufficient to keep the player out of the game.

| | |
|---|-----|
| Dislocation of elbow | 1 |
| Teno-synovitis tendo-Achilles | 1 |
| Dislocation of xiphoid cartilage | 1 |
| Injury to back ⁶ | 9 |
| Synovitis of knee ⁷ | 3 |
| Sprained ankle | 13 |
| Strained muscle of side | 2 |
| Crushed finger | 1 |
| Contusion of knee | 1 |
| Contusion of side | 1 |
| Fractured rib | 5 |
| Rupture of internal lateral ligament knee | 1 |
| Dislocation of shoulder ⁸ | 2 |
| Concussion | 19 |
| Ruptured muscle | 6 |
| Dislocated semilunar cartilage | 10 |
| Contusion of elbow | 1 |
| Compound dislocation of fingers | 2 |
| Traumatic valgus | 1 |
| Fracture of zygoma | 2 |
| Torn ear (sutured) | 3 |
| Broken nose | 7 |
| Fracture of rim of pelvis | 4 |
| Fractured clavicle | 1 |
| Bruised hip | 2 |
| Fracture of semilunar of wrist | 1 |
| Dislocation of acromial end clavicle | 11 |
| Fractured finger | 4 |
| Broken second cervical vertebra | 1 |
| Dislocation of inner end of clavicle | 1 |
| Rupture of biceps of leg | 1 |
| Middle meningeal hemorrhage | 1 |
| Hematoma of ear | 2 |
| Fracture of metacarpal bones | 3 |
| Sprained elbow | 1 |
| Total | 145 |

It must be accepted that the figures of the injuries received during the previous years are within the facts. The players were most of them extremely conscientious about answering the questions in the circular letter. On the other hand, the game appears to breed such a contempt for physical pain that many injuries which would appear severe to the ordinary individual were considered trivial by the players. For instance, one man, in answering the circular letter, answered the question, "How many injuries were received during 1905?" "Absolutely none whatever," although at that time he was being treated by one of us for a very large hematoma of the ear and had previously received a partial dislocation of the outer end of the collar bone, and an (unrecognized) fracture of a metacarpal bone. Our own record of the serious injuries of this year (1905), however, is complete.

The following general methods of treatment of the ordinary, acute injuries were adopted. There was almost no fixation of injured parts, except fractures and dislocations, throughout the entire season, as the men were anxious to return to play and it was our belief that fixation usually unduly prolongs the time of convalescence. In the ordinary sprains of joints and notably in the cases of acute knees, heat was used very extensively, either by means of hot bathing or by means of the "baking machine." A large part

⁶ The character of the injuries was variable, but includes what is ordinarily spoken of as "strained back," which oftentimes leads to very marked disability for a considerable length of time.

⁷ These were cases in which no cause for the synovitis was made out and does not include the synovitis following, for instance, a dislocated semilunar cartilage. The number of these cases was agreed by everybody to be much less than in previous years.

⁸ In one case there had been a previous dislocation of the shoulder

of the acute injuries were treated by massage, with most remarkable and satisfactory results. We had, almost throughout the season, the attendance of a most efficient masseur, whose work was highly satisfactory. When a sprained or injured joint was unusually tender, partial fixation was accomplished by means of compression bandages, but in no case of joint injury was there fixation by splints, and in only two cases of ruptured muscle was complete fixation carried out. For partial fixation we used a heavy layer of sheet wadding surrounded by the so-called "Ideal" bandage, which was found extremely satisfactory, comfortable and efficient.

Certain classes of injuries were common and these are mentioned under special headings.

Head injuries.—Cases of concussion were frequent, both during practice and games. In fact, but two games were played during the entire season in which a case of concussion of the brain did not occur. There were several noticeable features in these cases. Frequently, the fact that a man had received a serious head injury was noticed by the surgeon from the side lines before it was recognized by the players. This was due to the fact that a player might, apparently, automatically run through a considerable series of plays before his mates noticed that he was mentally irresponsible. The mental state of the players who had concussion was variable, some being highly excitable and hysterical, others merely confused, and in a few cases, knocked completely unconscious. In every case there was a certain loss of memory, both previous and subsequent to the injury. The loss of memory previous to the injury varied from a few minutes to a week. In all cases also there was a loss of memory as to facts occurring for a variable time subsequent to the injury. For instance, it was common to hear a player ask if he had played the first or second half of the game. In all cases the loss of memory was greater at first than it was after a few hours. For example, the man who had lost his memory of events which occurred for a week before the injury, ultimately got to a point where he remembered everything up to within an hour or so. Players who had had concussion were at once carefully examined to exclude the possibility of middle meningeal hemorrhage and, during the earlier part of the season, were sent to their rooms or to their homes, with a companion, with strict orders that they were to be left alone at no time until noon of the following day. Later on in the season this method not seeming sufficient, the injured men were in every case compelled to go to the infirmary, where they remained over night. These precautions were taken to avoid the possibility of the occurrence of middle meningeal hemorrhage with delayed symptoms. One case of middle meningeal hemorrhage did occur.

Concussion was treated by the players in general as a trivial injury and rather regarded as a joke. The real seriousness of the injury is not certain. Our own experience with the after-effects of the cases is not sufficient for us to draw

any definite conclusions, but from conversation with various neurologists, we have obtained very various opinions in regard to the possibility of serious after effects.

Dislocation of the outer end of the collar bone.—Partial and complete dislocations of the outer end of the collar bone were extremely numerous and were received in a variety of ways, some while tackling in the open, but the greater num-

Fig. 1

Complete dislocation upward of the acromial end

ber of them were caused by the players having one shoulder caught in the pile with a mass of men falling upon the unprotected shoulder. In but two cases was the dislocation a complete one, and in one of those cases the player received it very early in the game and finished a twenty-minute half with the collar bone and the scapula entirely separated. He was extremely fortunate

Fig. 2

Same case as Fig. 1

to obtain no more serious results. One player on the second eleven played throughout the entire season with a complete dislocation received during a former season.

In all there were eleven cases, the majority of which were incomplete. Fig. 1 shows a case of complete upward dislocation. The acromial end of the clavicle is projected upward. Two factors

act to produce the deformity. The contraction of the trapezius muscle tends to draw the clavicle upward. The weight of the arm, deprived of the out-rigger support of the clavicle, pulls the shoulder (scapula and humerus) downward, inward and forward.

Dressing for dislocation of acromial end of clavicle, front view.

Fig. 2 shows the same case with the arm held out from the trunk which makes the deformity more prominent. In this case it was possible to place two fingers side by side in the gap between the clavicle and the acromion.

Treatment.—The reduction of this dislocation is simple. The shoulder is lifted upward and the clavicle is pressed down into place. On the other hand, the maintenance of reduction by the means ordinarily employed is extremely difficult.

Various dressings were tried, all of which proved more or less ineffective in holding the bones in the corrected position. The dressing shown in Figs. 3 and 4 is a modification of a dressing devised by Stimson in 1883 with the addition of a strap (A) to correct forward displacement of the shoulder.

The forearm is supported by a wrist sling (C). With the shoulder held in the corrected position, strap (A) of two-inch surgeon's plaster is started near the wrist, carried over the point of the elbow, which is protected by a pad, and back across the upper arm, and while the shoulder is held back in the corrected position, the plaster is carried upward to the base of the neck behind, or forward over the shoulder to the front of the chest. Strap (B) is then applied, starting on the front of the chest, going upward over the shoulder about an inch internal to the outer end of the clavicle, down the back of the arm, around the elbow and up in

front, crossing the first turn of the strap at about the middle of the clavicle, thence over the shoulder and to the opposite side of the back. The tendency to inward displacement of the shoulder is corrected by an axillary pad not shown in the picture. Outside the dressing a Velpeau bandage is applied. This dressing has been comfortable and effective in every case.

Figs. 5 and 6 show the result in a case of complete upward dislocation of the acromial end at the end of seven weeks. This case was complicated by subcoracoid dislocation of the head of the humerus on the same side. The deformity is very slight and the prominence is due largely to atrophy of the shoulder muscles from fixation. At present function is unimpaired. All joint motions are free and unrestricted with the exception of some difficulty in putting the hand behind the back, which is gradually disappearing.

Fig. 7 shows the dressing employed in cases of incomplete dislocation after the men had resumed playing at the end of two or three weeks. It was intended only as a support, the shoulder being protected by special pads. It proved effective, not a single case recurring.

Dislocated semilunar cartilage.—The number of these injuries also was large and they were received almost always in the pile and were due to a blow upon the outer side of the knee while the lower leg was fixed. Two men played through the season with dislocated semilunar cartilages which were known to have been received in other

Same, back view.

years, and in both cases their efficiency was very much impaired. Three men were entirely kept out of the play after receiving such injuries.

A method of reduction was employed which we believe to be new, and was found very effective. The patient lies flat on the back and flexes the

thigh firmly against the chest. In this position two advantages are at once apparent; the thigh is absolutely fixed, and the knee can be completely flexed.

If the leg is now rotated outward and abducted,

Result of case of complete upward dislocation at the end of seven weeks

the inner articular surfaces of the joint are separated. The leg is now rotated inward, and at same time extended, the fingers of one hand pushing the cartilage into place. Reduction is usually accomplished before the foot has completed the arc shown in the figure.

This method of reduction was successful in all of the cases in which it was tried.

Dressing for semilunar cartilage. After reduction a pad is applied just internal to the patella over the point at which the cartilage escaped from the joint. It is important to note that this point is not over the lateral aspect of the joint, but is farther forward, i. e., antero-internal. The pad is held in position by cross strapping of narrow surgeon's plaster. It was found that a single series of narrow plaster strips applied as shown in Fig. 11 was often as effective in holding the car-

Same case with arm partly extended

tilage in position and had the additional advantage of allowing more free flexion of the knee, as the strapping shown in Fig. 12, so that the men could run and resume play almost at once. This dressing was used in ten cases of displaced car-

tilage and in no case did the cartilage slip out, even during play.

The advantages of the above described methods we believe to be, the absolute simplicity of the dressings, the ease with which they can be applied and the small cost of the materials. They have been tested in a sufficient number of cases under conditions not altogether ideal, and have proved effective in every case. The simple strapping of the knee for displaced cartilage succeeded in cases where elaborate and expensive apparatus failed.

Fractures. — The number of fractures received was considerable, although nearly all were of minor severity. In almost every case the fractures were X-rayed. In many cases the men were allowed to play after receiving fractures, at a time when patients ordinarily would be willing to protect themselves, although in every case the players were very carefully guarded by special apparatus. In no case did a man who had been allowed

Simple elastic dressing

to play a relatively short time after the receipt of a fracture receive a refracture.

Ruptured muscles. These injuries were common and affected either the quadriceps extensor of the leg or the hamstring muscles. Ruptures of the quadriceps were especially common among the heavy men and in many cases were due apparently entirely to the muscular exertion of quick starting. In some cases and especially in the severer ones the injury appeared to be due to a violent blow upon the thigh of a man running at speed, with the muscles tense. Ruptures of the hamstring muscles, which also are common among sprinters, were in every case due to muscular exertion alone. These cases were treated by heat and massage and moderate exercises, such as walking. In two cases, however, the injury was so severe as to require fixation by splints.

Sprained ankles. — The injuries of this type were not, upon the whole, severe, and in no case was a player kept out of the scrimmage for any considerable length of time. The ankles were treated by heat, massage and by strapping, although in one case a special apparatus, somewhat resembling a valgus shoe, was worn by a player throughout the greater portion of the season.

Fig. 8

Reduction of semilunar cartilage, first step; flexion of the thigh.

Synovitis of the knee. — These cases, except those due to a loose semilunar cartilage, were not numerous, and were treated by heat, both hot water and baking, by massage and by compression. The results obtained from these measures were surprisingly good and the time out of play was extremely limited.

Broken noses. — In practically every case there was a fracture, not only of the external but of the internal nose, and all those cases were sent to a nose specialist.

Fig. 9

Reduction of semilunar cartilage, second, third and final steps, outward rotation of leg, abduction of leg, inward rotation of leg and extension.

The opinion of the players was that the injuries received were, on the whole, not severe. The real severity of the injuries, however, may be estimated in a number of ways:

(1) By the length of time during which players were incapacitated from taking part in the game. In answer to the circular letter the players stated the number of days that they had been kept out of the play by their injuries. The aggregate number of days during which players were incapacitated previous to this season was 864. The aggregate number of days during which players were kept out of the play during the season of 1905 was 1,057 days, that is an aggregate practically of three years. In regard to the apparent excessive amount of incapacity during the season of 1905, it must be borne in mind that players who had received injuries were not allowed to play until they had received the permission of the surgeon in charge, and, as has already been stated, great caution was exercised in keeping men out until they were thoroughly fit to play.

Cross strapping

(2) Another index of the severity of the injuries is the number of days that players were kept away from scholastic or college duties. From the answers to the circular letter it appears that previous to 1905 players were kept away from school or college a total of 128 days; during the season of 1905 they were kept away from college duties a total of 175 days. These figures are based upon the players' own written statements, but have not been verified by the college record and probably do not represent more than the facts.

(3) Another index of the severity of the injuries is shown by the amount of surgical supplies which were required during the season to properly dress and take care of the injuries. The cost of those supplies for the past season was (including the sterilizer which cost about thirty dollars) two hundred and twenty dollars.

A final index is the answer of the players as

to whether their recovery from injuries was complete, at the time the circular letter was sent out, a few days after the close of the season. One hundred and ten answers were received to 150 letters, and of those 110, 35 acknowledged that they had not entirely recovered from their injuries at that time. Besides those 35 who acknowledged that they still were suffering from a certain amount of disability or discomfort, it is known to us that many of the men who said that they were entirely recovered are suffering from injuries of more or less permanence. For instance, one man said that he had entirely recovered "except for a slight loss of vision." Another said that he had completely recovered "except for a slight dullness in the side of his head, with a bloodshot eye." Another reported that a loose semilunar cartilage was "absorbing," but "still in evidence." No one seems to be in a position to settle with certainty the question as to whether there is any possibility of later effects from concussion. Many of the joint injuries are of such a character as to be likely to be progressively worse and many of the injuries to the shoulder are certain to cause some disability in later years.

The question arises, Is it possible to avoid these injuries as the game is now played? Many of the players claim that many of the injuries are avoidable. This year special precautions were taken to avoid the occurrence of injuries. Men who were known to be candidates for the squad

before the violent work began, and special pads and armor were provided in sufficient quantities to protect the players as far as possible. In spite of these special precautions it is claimed that the number of injuries was excessive. It was noticeable that the injuries came in certain groups. In the early days of the practice the number of

Single strapping, leg flexed.

Single strapping

were notified early in the summer to begin to get into good physical condition before reporting for football in the middle of September. The scrimmaging was not begun as early this year as is usual, in order to harden the men up as much as possible

strained and ruptured muscles was very large, especially among the heavy men, so that almost no one of the heavy men escaped. Then came a period of sprains and bruises during the early days of the scrimmaging. Then came a long list of mixed casualties, and it is true that the number of injuries at the end was relatively small, although some were of a severe character, showing, apparently, a survival of the fittest. It does appear that expert players do protect themselves from injury in a measure, but one of us, two weeks before the Yale game, made out a list of twenty-two men from whom it was certain that the eleven which was to play against Yale would be chosen. Only one man played in the Yale game who was not on that list and he had previously twice been injured. Among those 22 men, at the time the list was made out there had occurred 24 injuries, such as are included in the table, although there were two men who at that time had been uninjured this year. A fracture of the ribs, a fractured nose and a dislocated semilunar cartilage, as well as other injuries, occurred among those 22, after that list was made out. Of the 150 men who were on the squad, only 30 claimed to have received no injuries prior to 1905. It seems to us that no skill is sufficient to protect a man who plays the game long enough. The mental attitude of the players is interest-

ing. The game inculcates marked indifference to physical pain, which is a desirable thing. It also appears to educate the men to a marked degree of indifference to the welfare of the body, in comparison to a mere game, which seems to us not so satisfactory. In many cases it was impossible to make the players see the severity of the injuries they had received, and in many cases where men were forbidden to play unless their parents assumed the responsibility, their parents appeared equally indifferent. The difference in the point of view between schoolboy players and players on the university eleven is very great. As has been noticed by us in surgical attendance upon schoolboy elevens, the schoolboy responds to injury much as the ordinary patient does, while, it seems to us, that the men who survive to play upon the university eleven are to a very large measure those men whose nervous system does not readily respond to pain.

An accurate comparison as to the relative proportion of injuries received by men playing football and those taking part in other major sports would be interesting, but we have not the facts to make an accurate comparison. One of us, however, has had a very intimate knowledge of college baseball for the past seven years and there is no question but that, while a man may be seriously injured in playing baseball, the relative number of injuries is incomparably less in baseball than it is in football. We believe the same to be found true in rowing and in track games.

Conclusions.—In consideration of the above facts we believe that the following conclusions may be drawn:

(1) The number, severity and permanence of the injuries which are received in playing football are very much greater than generally is credited or believed.

(2) The greater number of the injuries come in the "pile" and not in the open plays, although serious injuries are received in the open.

(3) The number of injuries is inherent in the game itself, and is not due especially to close competition, as is shown by the fact that the proportion of injuries received in games and in practice is about the same.

(4) A large percentage of the injuries is unavoidable.

(5) The percentage of injuries is incomparably greater in football than in any other of the major sports.

(6) The game does not develop the best type of men physically, because too great prominence is given to weight without corresponding nervous energy.

(7) Constant medical supervision of the game where large numbers of men are engaged is a necessity and not a luxury, although it is a question if a game, requiring the constant attendance of two trained surgeons, is played under desirable conditions.

(8) The percentage of injury is much too great for any mere sport.

(9) Leaving out all other objections to the game, ethical and practical, the conditions under

which the game is played should be so modified as to diminish to a very great degree the number of injuries.

FRACTURES OF THE SUPERIOR MAXILLARY BONE CAUSED BY DIRECT BLOWS OVER THE MALAR BONE. A METHOD FOR THE TREATMENT OF SUCH FRACTURES.*

BY HOWARD A. LOTHROP, A.M., M.D.,

Instructor in Surgery, Harvard Medical School; Assistant Visiting Surgeon, Boston City Hospital.

THE variety of fracture under consideration is generally classed as a fracture of the malar bone involving either its body or the zygomatic arch. These fractures are the result of direct violence and, as will be pointed out later, the lines of fracture are chiefly in the superior maxilla.

Anatomy.—Because of its situation the malar bone is frequently exposed to direct violence, such as blows or falls. This bone and the structure which supports it are formed so as to withstand considerable violence without fracture. The body of the malar is moderately thick and it is supported by four processes radiating in different directions. Running posteriorly is a process which unites with one from the temporal bone so as to form the zygomatic arch. This arch forms a strong support for the malar and gives origin to a part of the masseter muscle and it is in close proximity to the temporal muscle. The arch alone may be fractured by direct blows from comparatively sharp objects but such lesion is uncommon. As a rule there is a single line of fracture of the arch accompanied by a depression of the body of the malar itself and the essential fracture is that of the superior maxillary bone.

The superior maxilla is an irregular-shaped bone presenting strong borders and processes and thin surfaces. Upon the strong malar process of the maxilla rests the malar bone and further support is given the malar by its radiating frontal, maxillary, zygomatic and orbital processes. The surfaces of the maxilla which concern us are comparatively thin and are named according to the direction in which they face, namely, orbital, zygomatic and facial. Bounded by these thin surfaces is the cavity of the maxilla known as the antrum of Highmore. It is lined with mucous membrane and its only outlet of communication is with the nasal cavity. The apex of the antrum is at the malar process of the maxilla. The infra-orbital nerve appears just below the maxillary process of the malar and is frequently injured in these fractures as are the anterior dental nerves which follow grooves in the facial wall of the maxilla.

Symptoms. (a) *Fractures of the zygomatic arch alone.*—These are rare and are the result of direct violence caused by comparatively sharp objects. The arch must fracture in two places; the body of the malar remains intact. In addition to the history of the possible bruising of soft parts, the examiner may detect a local depression although the deformity is not very marked.

* Presented at a meeting of the Clinical Society of the Boston City Hospital, December, 1903.

The finger in the mouth may detect a difference in the zygomatic arches of the two sides. Mastication is usually painful. The discomfort as a whole is very moderate.

(b) *Fractures of the superior maxilla and zygomatic arch with depression of the malar.*—This injury is not uncommon. It is the result of direct blows over the malar or the result of falling on some hard substance. The violence is transmitted directly through the malar and the displacement of this bone depends somewhat upon the direction of this violence. The line of fracture is subject to little variation. It involves the facial surface of the maxilla starting just below the extremity of the maxillary process of the malar, passing through or near the infra-orbital foramen; thence, obliquely downward and outward below the malar process of the maxilla on to its zygomatic surface. There is necessarily a line of fracture in the very thin orbital surface. The tendency is to crush the malar into the maxilla so that the former is depressed and impacted, remaining in this position unless interfered with. In most instances the zygomatic process fractures in one place. Crepitus is unusual. The deformity is characteristic. The asymmetry of the face should be observed from in front, behind and above. Generally the skin remains intact but occasionally it is wounded. Soon, however, there is local swelling of soft parts, often sufficient to cause the bony deformity to be overlooked. Thus, frequently cases are not diagnosed until a subsequent time. An early common symptom is nasal hemorrhage from the injured side because of a wound in the mucous membrane of the antrum. The hemorrhage is transitory and very moderate. Furthermore, hemorrhage takes place into the surrounding tissues, such as eyelids and cheek, causing discoloration. There is very frequently subconjunctival hemorrhage, often involving the entire sclera. There is tenderness over the malar and vicinity. Mastication is painful because of the pulling of the masseter and pressure on the temporal muscle. There is frequently anesthesia in the distribution of the infra-orbital and anterior dental nerves, this passes off in time. By an early examination it may be possible to palpate the ridges on the facial surface of the maxilla made by the fragments. Comparison between the zygomatic arches examined within the mouth shows a narrower space on the injured side. Bimanual examination with one finger under the malar may occasionally reveal crepitus. Fracture of the nasal bones is sometimes a complication.

Course.—The discomfort suffered in these cases is usually no greater than that resulting from a simple contusion; this is due largely to the fact that the fracture is generally an impacted one. In due time the swelling subsides leaving a varying degree of asymmetry as the only end result when left untreated. Finally all sensation is restored. Occasional complications are abscess of the cheek and of the orbital fossa. Empyema of the antrum of Highmore is a most unusual complication.

Treatment.—As already mentioned, if fracture is unsuspected and these cases are treated as contusions, recovery will be complete in every respect except that there will remain a varying degree of permanent deformity. The usual local and general palliative measures should be resorted to for the relief of the subjective symptoms. Care in the diagnosis of all injuries in the vicinity of the malar bone should enable the examiner to determine whether a fracture is present or not and if a fracture is made out, operative interference should be resorted to for the purpose of restoring the malar to its normal position.

Operative treatment.—The aim of operative treatment is to restore fragments, and this object may be accomplished by different methods:

(1) An incision has been made over the malar for the purpose of inserting an instrument into this bone by means of which it may be drawn out into place. The objections to the procedure are sufficient for its discontinuance. These are the persistence of a scar, and inability to maintain the restored position of the malar until bony repair is complete.

(2) Blunt instruments have been introduced by the mouth under the zygomatic arch, and by this means the malar has been elevated to its proper place. This method is less objectionable than the first because it obviates any subsequent facial scar. The disadvantages consist in the fact that only the malar and zygomatic arch are raised without there being any very satisfactory means of retaining these parts in place. The depressed portion of the maxilla is not elevated while, on the other hand, these maxillary fragments could be used (as in the following method) for the subsequent support of the malar. This method is sometimes followed by troublesome abscess of the cheek in consequence of infection of the wounded soft parts in the vicinity of the zygoma.

(3) This method has been used by the writer for several years. It consists in elevating the malar together with the various fragments of the maxilla, working through a small opening in the canine fossa whereby all elevating force is directed from the surface of the antrum outward. The writer believes this method offers the following advantages: The degree of trauma of soft parts produced is comparatively slight; all depressed fragments can be elevated; their position can be maintained; there is no risk of subsequent empyema of the antrum; such procedure does not disable the patient more than a few days so that he may resume his work; there is no facial scar; the facial asymmetry, if such persists, may be reduced thereby to a minimum; and finally, neglected cases may be treated successfully even after the lapse of several weeks.

The technique of operation is as follows: The patient should be under the influence of a general anesthetic, the administration of which should be continued during the operation with a method by which vapor is conducted to the air passages through a slender tube in order not to interfere with the operator while he is working about the

mouth. The best position for the patient is sitting erect in a chair which supports the back leaving the head free to be moved by an assistant in different directions. The face should be washed carefully with soap and water, rinsed off with a sterile solution and then should be washed with a 70% solution of alcohol. The nostrils may be cleaned in a similar manner, but there is no intra-nasal preparation. Prior to the administration of the ether, the teeth should be cleaned and the patient should gargle with some mild solution. The hair should be covered with a sterile rubber cap or towel and a sterile sheet should cover the rest of the patient, leaving only the face exposed.

Operation.—The cheek on the affected side should be raised and pulled to one side so as to expose the canine fossa. This may be done by means of the finger of the operator or by a retractor. A horizontal incision about three quarters of an inch long should be made along the line of junction of the mucous membrane of the alveolus and the cheek in the uppermost portion of the canine fossa. The whole incision is posterior to the canine ridge and is at the highest point of the vestibule of the mouth. The incision should be carried down directly to the bone and the soft parts slightly freed by means of a periosteum elevator. At this juncture one may feel the line of fracture in the anterior wall of the maxilla. The director should now be pushed through the fissure or, if none be detected, through the intact bone into the antrum of Highmore. The director should be kept in this position and, guided by its groove, the operator may pass larger instruments into the antrum tending, meanwhile, to force the fragments upward and forward. The opening should be made sufficiently large to pass a No. 24 French sound. With elevators of suitable size and shape the depressed portion of the anterior wall of the maxilla may be elevated. Then a sound is introduced and its tip carried to the apex of the antrum, that is, directly opposite the malar bone. The tip of the sound seems to engage naturally at this point. The head should now be held erect and firm by assistants. Both hands of the operator should be placed on the sound, one being about half way down and resting on the side of the face in order to give support and steadiness. Gradual increase in pressure should now be exerted on the sound, the force being directed in such a manner as to tend to replace the malar in its normal position. As the malar resumes its normal position the asymmetry will be seen to disappear. With one hand holding the sound and the other placed over the malar, free mobility will now be observed for the first time. By means of the sound and the other elevators all fragments may be replaced. There will be a moderate degree of hemorrhage as a result of this manipulation, all of which ceases shortly. The finger placed on the skin over the malar and over the region of the anterior wall of the maxilla will serve for a guide as to the completeness of the reposition of fragments. Finally, introduce a rather

broad instrument through the opening into the antrum with its tip directed toward the malar so as to hold this bone in position. Then long and very narrow strips of iodoform gauze and sterile gauze should be introduced carefully so as to pack the antrum. These strips should fill up first the malar end of the antrum, gradually approaching its nasal surface. One must be careful not to push back the fragments of the maxilla and also not to force gauze in between the maxillary surface and the cheek. The ends of all of these narrow strips should be left just protruding at the incision in the vestibule of the mouth. When properly packed the position of all fragments may be maintained. No external dressing should be applied.

During recovery from the anesthetic the patient should be watched carefully so that he does not lie on the affected side of his face or press upon this region with his hand. He should be left to himself only when he has thoroughly recovered from the anesthetic so that he may not unconsciously interfere with the replaced bones. It is preferable that he remain in bed one or two days and after that he should be allowed to sit about in a warm room. He should be given ordinary simple diet. About every four hours it is wise to use a simple cleansing gargle and mouth wash. No intra-nasal treatment will be called for. There will be moderate edema of the cheek on the affected side and perhaps of the lower eyelid. Occasionally there is an increase of the subconjunctival ecchymosis. Local discomfort, if any be present, may be alleviated by light wet compresses. On the fourth or fifth day all the gauze may be removed from the antrum. This procedure generally causes but little discomfort and if there be any hemorrhage at this time it usually subsides in a moment. In cases treated by the writer subsequent packing has not been necessary, either to control any hemorrhage or to maintain further the position of the fragments. On the two following days the antrum may be irrigated through the buccal wound with a warm saline solution holding the head forward so that the fluid will escape through the mouth and nostril. At the end of about a week the incised wound will be healed and no further local treatment called for. During the first week there may be a certain amount of serous discharge from the nose on the affected side, but this subsides at once without further trouble. At the end of about ten days all local swelling will be gone. The tendency to relapse in these cases is very slight and when the end result is complete the degree of asymmetry is imperceptible or noticeable only when the patient is observed carefully. The wound in the mouth heals very rapidly and it is a fact that fractures of the superior maxilla, the result either of the original trauma or of operation only exceptionally are followed by empyema of the antrum.

The following cases are examples of the lesion under consideration treated by the method just described. They were patients operated by me at the Boston City Hospital on the services of

Dr. W. P. Bolles and Dr. H. W. Cushing to whom I am indebted for the privilege of reporting them:

CASE I. Male; thirty-six years old. About three weeks prior to entering the hospital this patient was attempting to hold a struggling horse when he was struck on the left cheek by the horse's head. This was followed by considerable swelling during the next two days. He sought no particular medical treatment until about two weeks after injury when he went to the out-patient department of the hospital on account of extensive swelling of the face. This swelling was due to an abscess which formed in the cheek. A small external incision was made to evacuate pus and the wound left open for drainage. No fracture of the maxilla was suspected at this time, but it was discovered as the swelling subsided. On account of fracture he was admitted to the hospital. When I saw him, about four weeks after his injury, the swelling had nearly disappeared but there was still a small persisting sinus in the cheek where the abscess was opened. About four weeks after injury he was operated on in the manner already described and the bone replaced without difficulty. The operation wound in the mouth was healed in a week. No nasal or antrum complication followed. It was about three weeks before the wound in the cheek healed. Since then patient has remained perfectly well and the degree of asymmetry of the malar bones is scarcely perceptible.

CASE II. Male, thirty-one years old. About one week ago patient was struck a single blow with a fist just below the left eye so as to include the nose and left malar bone. Patient states that there was considerable nosebleed at the time and that since then the upper teeth to the left of the median line feel numb and that there is numbness of the skin below the left eye. Eight days after this accident he entered the hospital for operation. Examination at this time showed much depression over the left malar so that a concavity rather than a convexity presented. There was still some subconjunctival ecchymosis. The left nasal bone was much depressed. No edema persisted. The finger in the mouth carried under the left zygoma detected a very narrow space compared with the opposite side. There was the sensory disturbance of which patient complained. He was operated eight days after accident in the manner described and discharged from the hospital in seven days. When seen some months later there was no disparity in the two malar bones.

CASE III. Male, thirty-six years old. Patient states that about two weeks ago he was struck on the left cheek by a small stone tied to a string which was thrown by a child. He was dazed for a moment. The skin was not injured, but the accident was followed by swelling and discoloration about the malar bone, together with bleeding from the left nostril. Ten days later there was subconjunctival hemorrhage. In the course of a few days the swelling had subsided and then he observed that the cheek bone was depressed. He noticed that the left side of the nose and face below the eye including the upper lip were numb. Since accident there has been considerable discharge from the left nostril. When seen by me there were to be observed the subconjunctival hemorrhage and the asymmetry. There was no edema, but there was anesthesia as noted. He was suffering no particular discomfort. Sixteen days after accident he was operated on in the manner described and the convalescence was without complication. The malar was fully restored.

CASE IV. Male, thirty years old. About nine days ago patient fell on a stove striking the left side of his face. This was followed by nosebleed which occurred in three days. When seen for the first time on the ninth day there was still considerable swelling of the tissues about the malar and left eye. There was a small abrasion here. There was subconjunctival hemorrhage and there was obvious bony asymmetry which was clearly due to a depression of the body of the malar. By the month it was possible to detect the line of fracture in the maxilla. Fourteen days after accident the malar was elevated by introducing a No. 24 French sound into the antrum by the method described. The end result was satisfactory.

CASE V. Male, twenty-nine years old. Patient states that he was struck on the right cheek by a man's fist and then by a broom handle. This accident was followed by nasal hemorrhage and anesthesia of the right cheek and right side of nose. This patient sought medical advice at once and was treated for contusions, fracture not being suspected apparently. After the swelling had subsided the bony asymmetry was observed and I saw him twenty-four days after his injury. All subjective and objective symptoms had disappeared except the bony disparity and this was sufficient for him to ask to have it corrected. Consequently he was operated on twenty-six days after his injury in the manner described above. It was perfectly easy to raise the fragments of bone even after this lapse of time and the case presented nothing unusual. The result was satisfactory.

CASE VI. Male; twenty-five years old. This patient was a fireman, and, while passing an electric pole in answering an alarm, the wagon slipped so that the pole struck the left side of his face. He was thrown to the ground and rendered unconscious and was brought to the hospital at once. Examination showed that he was suffering from concussion of the brain. There was a lacerated wound over the left eyebrow which connected with a small depressed fracture of the left supra-orbital ridge. This was too slight to call for interference and the wound was sutured. There was marked depression of the left malar bone. There were no signs of fracture of the vault or base of the skull. The usual signs of depression of the malar due to fracture of the superior maxilla were present. Three days after accident the left malar bone was elevated according to the method described above and the result was perfectly satisfactory.

CASE VII. Male, eighteen years old. This man was brought to the hospital with the history of a fall from a car. There were two scalp wounds over the left temporal region. There was very moderate swelling of soft parts over the left malar. There was nosebleed from the left side. On the following day there was left subconjunctival hemorrhage. The malar bone was much depressed and a ridge could be felt on the facial surface just below the lower margin of the orbit. The diagnosis was made of scalp wounds and fracture of superior maxilla with depression of malar bone. Patient consented to have the malar bone elevated. The antrum was opened in the usual manner, but when the sound was introduced into the antrum, notwithstanding that an unusual amount of force was used, the malar bone was not dislodged. It was thought was not to attempt greater force. From the fact that patient was operated two days after accident it was obvious that we had to deal rather with a very old fracture of which patient seemed to have no knowledge or with an asymmetrical development of the facial bones. The asymmetry was very noticeable. The wound in the nostril healed rapidly without any complication.

PUERPERAL SEPTICEMIA.*

BY E. H. STEVENS, M.D., CAMBRIDGE, MASS.

My excuse for bringing this subject before you this evening is, first, that while puerperal septicemia is practically a thing of the past in all well-managed lying-in hospitals, it is a disease which is still found in general practice not infrequently, causing many deaths and a vast amount of suffering the world over. In my opinion the number of women dying from septic poisoning after childbirth is much larger than one would be led to suppose from an examination of the death records. I find recorded in Cambridge, with a population of 95,000, only 20 deaths as having been caused by what can be classed as puerperal septicemia during the past ten years. I feel sure that this would be found to be far below the number if the exact truth were known.

My second reason for presenting a paper on the subject is that the treatment advised in this class of cases by many writers of the present day is so much at variance with what I have been in the habit of carrying out and advising during the past thirty years, that I have wondered if I have been wrong all this time. I wish to report two cases seen in consultation which represent two distinct types of puerperal sepsis.

Mrs. A., aged twenty-three, was confined April 2, 1903, with her second child. The delivery was normal in every way. There was no noticeable injury to the soft parts. Everything progressed well until the morning of the fifth day, when the patient complained of severe headache with general discomfort all over. The same afternoon the temperature was found to be 103; the pulse 120. For the first time the lochia was noticed to be foul smelling and scanty. During the night the patient was awakened from a sound sleep by a severe chill which was followed by sweating. The temperature taken just after the chill registered 105. Seen by the writer in consultation the next morning, when the following conditions were noted: A very foul odor pervaded the room, the patient's face wore an anxious expression, the skin was hot and dry, tongue slightly coated, the breath having a sweet, disagreeable odor, pulse 130, temperature 105.8. A second chill came on during the examination when the temperature rose to 106.2, the pulse going to 150. The chill was followed by profuse sweating. The napkin showed lochia to be pale, scant and very foul. An hour later, after free stimulation by brandy, the patient had sufficiently rallied for further examination. The uterus extended well above the pubis, and was slightly tender on pressure which brought on a slight contraction, expelling a quantity of bad smelling fluid. A Reynolds large-sized curette was introduced into the uterus and a large quantity of broken down blood clots with sloughing, granular matter was removed, after which the uterus was thoroughly irrigated with a weak formalin solution. It was recommended that the irrigation should be repeated three times during the next twenty-four hours. Forty-eight hours afterwards the temperature was normal and remained so. From this time on convalescence was uneventful.

The second case was seen in consultation with Dr. Stickney who has kindly furnished me with his notes of the case, up to the time when she came under my care at the Cambridge Hospital;

Mrs. P., twenty-one years, primipara. Labor thirty hours, low forceps, delivery 1.30 a.m., June 26, 1904. Small portions of placenta and part of membranes retained in uterus; these were immediately removed by the hand, and the uterus irrigated with a corrosive sublimate douche, while the hand was in the uterus; every part of the secundaries was removed, and the interior of the uterus felt perfectly smooth and clean. The first vaginal examination was preceded by a corrosive sublimate douche and all examinations made with rubber gloves. Although the labor was instrumental the perineum was not injured and the uterus contracted normally. June 26, 2 p.m., temperature 100. During the night of the 26th there was a chill, morning temperature 102, pulse 100, bad headache, lochia very slight. June 27, morning temperature 102½, afternoon temperature 103+, cheeks flushed, head ached badly, pulse 120, tongue coated, patient thirsty. Lochia sweet and very slight. June 28, restless night, pain general throughout abdomen, but worse in left lower portion, breasts not tender, milk fair quantity, nipples not cracked, temperature 104, pulse 120. Patient has a general septic look. Blood showed white count 54,000. Patient seen by Dr. Stevens. Careful examination of vagina and uterus, and no origin of sepsis found. June 29, woman's condition no better, morning temperature 104.6, pulse 120; afternoon temperature 104.7, pulse 125, breathing rapid. Was sent to the Cambridge Hospital in the evening.

On entering the hospital at 10 p.m. on June 29 she was found to be suffering from pain in the lower part of the abdomen, which was distended and tender. The uterus was freely movable and well contracted; nothing could be made out in the broad ligaments. Nothing abnormal in lungs; a soft systolic murmur was present, heard loudest over apex of the heart. (Dr. Stickney is sure this was not present in the morning.) Liver not enlarged, spleen not palpable, very anemic, breathing rapidly, temperature 103.6, pulse 130; lochia moderate, no odor; urine by catheter, specific gravity 1.026, large trace of albumin, no sugar; blood count 37,800 whites, Hb. 40%, iodine reaction positive.

At a consultation held soon after entrance, it was decided that the case was generally septic and did not demand surgical interference. Treatment 40 cc. anti-streptococcus serum by injection; brandy one-half ounce by mouth every two hours, bowels to be kept freely open by mag. sulph. June 30, had slept four hours, a mild delirium present. Brandy continued; 20 cc. serum given. From this time until July 14 the patient's condition changed but little. Eggs and milk with brandy were given freely and retained. All tenderness and distention of the abdomen disappeared three days after entering the hospital. Serum was administered on the first, second, third, fourth, sixth, seventh, ninth and eleventh days, in all, 80 cc. having been given. It was discontinued as the symptoms seemed not to be growing worse; in fact, many of the symptoms were better, such as disappearance of delirium, an increase in the amount of food ingested, lessening of the heart murmur. On the sixteenth day after entrance to the hospital the pulse and temperature went down, not to go up again. She left the hospital July 27 in very good condition. The heart murmur had entirely disappeared when examined on Oct. 4.

While the use of anti-streptococcus serum in this case proves little, the fortunate termination would encourage me to use it again in a similar case, even in larger doses.

Most of the more recent writers on this subject condemn the curette, advising strongly against

* Read before the Obstetrical Society of Boston, Jan. 24, 1905. This manuscript reached us too late for early publication.

its use, except occasionally. Williams, whose book on obstetrics was published in 1903, says:

"If the uterine cavity is perfectly smooth, a douche of several liters of boiled water or normal salt solution should be given, but curettage should not be thought of. On the other hand, if the interior is rough and jagged and contains more or less débris, it should be thoroughly cleaned out with the finger, after which an abundant saline douche should be employed. Curettage as a routine measure in all cases of puerperal endometritis is by no means to be recommended, for the reason that in most severe cases there usually is absolutely nothing in the uterine cavity which can be removed, and its employment can only do harm by breaking down the leucocytic wall which serves to prevent the invasion of the deep layers of the uterus by the offending bacteria. On the other hand, when the uterus contains much débris, its removal is more readily effected by means of the finger than by the curette.

"The routine use of bichloride or carbolic intra-uterine douches in the treatment of these cases is contra-indicated on several grounds. In cases due to virulent streptococci, an histological examination shows that the organisms have penetrated deep down into the tissues by the time the initial chill and rise of temperature occur. Under these circumstances the employment of an antiseptic douche is not rational, inasmuch as the germicidal fluid cannot possibly penetrate the uterine wall sufficiently deep to reach the bacteria, which are giving rise to the symptoms and upon which the further spread of the disease is dependent.

"What has been said concerning bichloride applies equally well to the other disinfectants. On the other hand their employment in cases of putrid endometritis is even less rational. In the vast majority of such cases simply cleaning out the uterus with the finger or curette, followed by a douche of sterile salt solution, will lead to a rapid fall of temperature and the amelioration of untoward symptoms. The object in giving a douche in these cases is simply to wash away the débris which has been left by the finger, and for this purpose sterile water or salt solution is far better than any antiseptic fluid.

"Unfortunately, up to the present time, the results of serum therapy have not proved more satisfactory than other methods of treatment."

Jewett, in the *Brooklyn Medical Journal*¹ of January, 1904, says about the curette:

"One of the principal causes of death in these cases is its indiscriminate use. The mortality with the curette is estimated at 22% to 50%, whereas in wholly neglected cases it would not be 20%. In three series of cases of streptococcus infection reported by Kronig, Savor and Williams, 38 in all, the mortality, under little or no intra-uterine interference was 5.75%.

"Its use is irrational; in milder forms of streptococcus endometritis the leucocytic wall bars diffusion of bacterial organisms; the curette breaks

down the barrier. In the severer forms no leucocytic zone is developed and streptococci are beyond the reach of the curette from the first. Here the curette opens lymphatics and veins anew and helps to reinforce the bacterial invasion. While the curette cannot be wholly condemned there can be no doubt that in the treatment of acute general puerperal endometritis the general results would be better if it were not used at all." In regard to irrigation he says: "The objections against the curette hold in general against the douche. It should be used but once, and then only as a part of primary cleansing. Except in the presence of loose débris there is no occasion for douching. When required, use only normal saline or boiled water, as its function is purely mechanical. Many deaths have resulted from mercuric and carbolic douching."

Davis and Montgomery of Philadelphia, Frye of Washington, D. C., S. C. Gordon of Portland, Me., Williams of Baltimore, McLean, Pryor and Boldt of New York, have all published papers taking a similar attitude toward the use of the curette.

Pryor reported 36 streptococcus cases with a mortality of 4 (or 11%) which he had treated by curetting and packing the uterus with iodoform gauze, then opening the posterior cul-de-sac widely and packing the pelvic cavity with iodoform gauze up to the level of the broad ligaments. The good results were probably due to the curetting. Recent literature shows a number of men, among them Mann of Buffalo, who have tried and recommended Pryor's method.

Caruso's alcoholic irrigation with two rubber tubes introduced into the uterus does not appear to show any better results than the regular methods of treatment.

Webster packs the uterus with gauze saturated in glycerinated formalin solution, renewed every twelve hours and preceded by irrigation with peroxide.

The objections to intravascular medication with formalin or other antiseptics are that the bacteria are not always in the blood and that germicides in sufficient strength to destroy them do serious injury to the elements of the blood. Collargol, however, is harmless and worthy of further trial.

The method of Fochier, injecting turpentine into the flank, Hoffbauer's treatment with nuchem with the idea of stimulating cell production, and Oelsner's rest treatment need only to be mentioned.

More or less has been said about hysterectomy, among the conditions where it may be considered are the retention of putrid placenta, suppurations, metritis, septic fibromatosis and severe injuries to the uterus. At the Fourth International Congress of Obstetricians at Rome in 1902 the general feeling seemed to be that hysterectomy for puerperal sepsis was rarely indicated.

The resection of infected pelvic veins has been advocated by Freund, Trendelenburg and other men in Europe, but it is practically untried in this country.

¹Trans. Am. Gyn. Soc., 1899.

C. S. Bacon of Chicago, in the *Jour. Am. Med. Assoc.*, April 3, says: "In saprophytic infection the removal of debris effects a cure; to do this use a dull curette and the douche. In true puerperal infection use the same measures, drainage, irrigation and curetting. But here the curette should be used with unusual care not to break down the protecting zones of leucocytes. After the uterus has once been cleaned, further temperature means extension beyond the endometrium — then, further local measures are useless."

Reynolds and Newell in their textbook state that

"If the intra-uterine involvement is limited to a very mild affection of the endometrium, or to decomposition of the uterine contents, the use of the intra-uterine douche may be sufficient to restore the parts to an approximately aseptic condition, and is then followed by prompt subsidence of the symptoms; but in the majority of cases it fails to remove the whole focus of infection. For this reason, and because the exact condition of the interior of the uterus can rarely be accurately ascertained, even by digital exploration through the patulous os, it is in general the best plan to resort to the use of the curette as a routine in all cases in which the uterine lochia are distinctly foul. This is justified by the fact that the careful use of the curette should never be productive of harm, while the positive results which almost invariably follow the thorough removal of the decomposed contents of the uterus are sufficiently marked to warrant a much more dangerous procedure. The theoretical objection that the curette makes a fresh wound, and that its use is therefore likely to be followed by an extension of the infection is to be answered by the fact that in practice this does not happen, if it is used early and preceded and followed by an antiseptic douche. The best curette for post-partum work is the large placental curette."

"If the disease is well advanced when the diagnosis is first made we must remember that nature's method of cure is by shutting off septic foci by an exudate of lymph, and great care must be taken not to destroy this natural protection. In neglected cases any large superficial masses which are present should be removed gently, without breaking down the defence, and then all local meddling must be absolutely given up. Too great emphasis cannot be laid on the importance of an early diagnosis, as this alone allows us to make a clean removal of the disease."

In regard to douches these authors say that "although intra-uterine injections are of limited value by themselves, they are of great use in keeping the interior of the uterus clean after the major portion of the diseased tissue has been removed by the curette." So much for the literature of the subject.

In the early eighties I began to wipe out the interior of the uterus, using an extra long pair of forceps which I had made for the purpose. This gave me much better results than those following the simple washing out of the uterus with a solution of bichloride of mercury or permanganate of

potash. When Reynolds gave us his long uterine curette I began to use it, and have never seen any good reason for not continuing to do so. In fact, the more cases I see the more I am convinced that such treatment is both safe and rational.

I have never been able to understand how the puerperal uterus can be cleaned out safely in any other way. Many recommend using the fingers for this purpose, but a uterus which is six to ten inches in depth cannot be explored without introducing the hand into the vagina, or even into the uterus itself in many cases, a procedure which to my mind is vastly more dangerous and less satisfactory than using the curette. I have found a weak solution of formalin to be safe and satisfactory for irrigating the uterus after curetting. Mercuric solutions, unless very weak, are not free from danger.

Fortunately, the milder type (the putrid) of puerperal sepsis is the most common form met with, but this, if left to itself, or in cases where nothing is done until the disease is well under way, becomes very threatening to the patient's life and it is only by the use of heroic measures that the cases are prevented from going on to sure death. The first case which I have reported is a good illustration of such a condition, and I feel sure that this patient's life was saved by the cleansing of the uterus.

If the disease can be recognized early, before the system has absorbed sufficient toxic material to become overwhelmed by it, much can be expected from a careful and thorough cleaning out of the uterus. It should be remembered that a rise of temperature in a woman having been delivered of a child means that something is going amiss, and that the most likely cause for such a rise of temperature is septic poisoning. Having this in mind, one should not wait until after a chill before learning definitely, if possible, the cause of the rise of temperature. Prompt treatment instigated now will prevent, in a majority of cases, serious trouble, while after a chill has occurred our efforts may be entirely without avail.

Clinical Department.

THE OBSTETRICAL SOCIETY OF BOSTON.

MEETING OF JAN. 24, 1905, DR. C. H. WASHBURN, JR. THE CHAIR.

DR. E. H. STEVENS read a paper entitled

PUERPERAL SEPTICEMIA.¹

DR. J. BAYST BLAKE: I would like to ask the reader whether it was not possible to have made a blood culture in some of these cases. In most of them a streptococcus infection was probably present, but if not it was hardly fair to expect much from an antistreptococcus serum.

DR. J. G. MUMFORD: It seems to me that the authorities quoted are rather ambiguous about their use of the curette; one speaks of its routine use and the other of its indiscriminate use, leaving it to be inferred that it is sometimes used.

¹ See page 12 of the JOURNAL.

Dr. F. B. HARRINGTON: While in recent years I have had no experience in fresh puerperal cases, in other uterine infections I like the method of wiping out the uterus rather than washing it out. At the Massachusetts General Hospital I see many cases of pyosalpinx where it is advisable to curette and in them it is my custom to wipe the uterus out. To be sure these cases of gonococcus infection are not quite the same as when a streptococcus infection is present. At the hospital we occasionally use the serum. I have just had a severe case of streptococcus phlebitis following a myomectomy. I allowed my house officer to use the serum, but there was no obvious effect. The patient was very ill and thoroughly septic, losing one eye from an inflammation of the choroid, but she finally recovered. Some ten years ago I saw a case of severe sepsis in a young colored woman following an abortion. After watching her some ten days I opened the abdomen and was somewhat surprised to find practically nothing beyond a marked engorgement of the veins of the pelvis due probably to a septic phlebitis. In such a case I should now certainly use the serum as that is practically the only hope we have.

Dr. W. F. WHITNEY: The first case of the reader might be more properly called "Putrid Intoxication" rather than "septicemia." The other case was apparently true septicemia.

Dr. F. S. NEWELL: I remember a case where the curette showed a pure culture of streptococcus, and streptococci were present in the blood yet complete recovery at once followed a single curettage.

I would divide these cases into three groups: First, putrefactive infection; cured by washing out. Second, mixed staphylococcus and colon bacillus infection; cured by curetting and washing out if the case is seen early enough. Third, pure streptococcus infection, or only slightly mixed, where the symptoms develop in the first twenty-four hours. This class of cases must be curetted at once, in the first forty-eight hours, or else the curette does positive harm by spreading the infection. I think these cases can be helped by washing out every four to six hours with salt solution and filling the uterus with alcohol to be absorbed. I believe also in washing the blood out with salt solution. I have seen the serum tried pretty faithfully but have not noticed any benefit nor has the use of the silver salts injected into the blood seemed to me of the slightest use. It is a good rule to make sure of the uterus being empty before it is possible to make a positive diagnosis.

Dr. J. G. BLAKE: From what I have seen of the serum treatment I am convinced that it is at least worth further trial. The great trouble is that it should be given in much larger doses than is customary and this has heretofore been prevented by the almost prohibitive cost. I am sure that if it were used in large quantities much better results would be shown.

Dr. W. E. BOARDMAN: Having been out of obstetrics for some years I am greatly surprised that there is apparently so much puerperal sepsis to be seen. It would seem as if it might be worth while to emphasize the necessity of the strict precautions that were in vogue a few years ago when at the Lying-in-Hospital sepsis was practically unknown.

Dr. STEVENS, in conclusion: As to the blood examination, any one who sees much of puerperal sepsis in consultation generally has to work pretty promptly, and cleaning out the uterus and using serum is apt to be necessary as a last resort. For that reason while in many cases I have had bacteriological examinations made I have generally pursued my treatment without waiting for their result. I began wiping out the uterus in the early eighties and when I reported some cases

at the Medical Improvement Society I was much criticized. At that time after wiping out with cotton I was in the habit of packing the uterus with iodoform gauze. This packing I have since abandoned as I am convinced it does harm. When I began to use the curette it seemed as if I were getting better results than with mere wiping. In putrid cases wiping is enough, or as good as curettage. I see at least a dozen cases yearly of puerperal sepsis as a consultant, so it must still be fairly common.

I was for a long time sceptical as to the value of the serum, but seeing its apparent great value in five cases of malignant endocarditis last winter where the patients were desperately ill and recovered after the use of serum in large doses—sometimes as much as 250 cc.

I was led to try it in puerperal cases and in some the happy result was more than could be expected. I agree with Dr. Blake that it is unfortunate that the expense makes it difficult to use the serum in the quantities that should be used.

I agree with Dr. Whitney that the putrid cases are not true septicemias, but I feel as I look back over thirty years of clinical experience that a little delay might have turned them into true septic cases.

In every large community the number of cases of puerperal sepsis, and deaths from it, for that matter, is still comparatively large. There is a feeling among the younger men that they will be held responsible for cases occurring in their hands and they are unwilling to recognize it and consequently do not treat it promptly enough. I was present last summer at a trial where the claim was made that sepsis was due to the negligence of the attending physician, showing that another danger has arisen to confront the physician.

Dr. E. H. STEVENS showed a specimen of untwisted tubal pregnancy.

Reports of Societies.

AMERICAN ORTHOPEDIC ASSOCIATION.

NINETEENTH ANNUAL MEETING, HELD IN BOSTON, JUNE 6, 7 AND 8, 1905.

(Continued from No. 26, p. 730, vol. cliv.)

SKINOGRAFIC REVELATIONS IN RACHITIC DEFORMITIES OF THE LEGS.

Dr. WALLACE BRANCHARD of Chicago said that the correction of over seven hundred cases of genu valgum and genu varum by rapid osteoclasis furnished opportunities for many skinographic comparisons before and after obliteration of the deformities. Corrected knock-knee tibia had uncorrected bow-leg femurs, thus producing bow-legs; conversely, corrected bow-leg femurs had dislocated knock tibiae, creating knock knees. These have been designated "transference cases." Unsuspected unilateral coxa vara had been revealed by the correction of unilateral knock knee. Coxa vara is frequent but covered by more apparent deformities. A weak epiphyseal attachment caused one epiphyseal cysts in the use of the Gatten osteoclasis. This was the only instance in over three hundred supracondylar osteoclasis. Skinographs of a femur revealed an acute angle at the fracture point and the osteoclasis a longitudinal line bisecting over the head and impacted sides. A dark shadow marked the extent and degree of myelitis. Skinograms of femurs showed only the slightest shadows after extensive fracturing and redressment. Skinographic studies of a number of cases representing the varying types of rachitic deformities of the legs were presented.

A STUDY OF BOW-LEGS.

DR. JOHN DANE of Boston read this paper, in which he stated that he wished to question the accuracy of the belief that the deformity in bow-legs is an outward bowing. The question of an outward or an inward bowing he regarded as a question of what was the proper lines to measure from. If a vertical line down the shaft of the femur is taken, then the tibia is bowed inwards. This bowing is probably caused by the cross-legged position assumed by the child before it begins to stand. The action of muscles could not produce such a bowing as has been contended, because before producing such a condition they must of necessity produce an equino-varus. After the tibiae once curved, the altered statics lead to abduction of the femora, and this predisposes to anterior bowing of the shaft and coxa vara.

DISCUSSION.

DR. H. AUGUSTUS WILSON of Philadelphia asked for some expression of opinion as to the question of spontaneous cure in bow-legs.

DR. R. H. SAYRE of New York said that for several years he had observed that, as described by Dr. Dane, the curve in bow-legs most often occurred at about the point of crossing of the legs, but it had not occurred to him before that the cross-legged position might be an etiological factor. Also he had observed in cases of anterior bow the curve occurred at the point on the legs where they projected beyond the lap of the another, and considered that the weight of the unsupported foot and leg was a cause in producing the bow. One case was reported where there was spontaneous recovery from bow legs, but such cases were considered rare. In the correction of such deformities his preference lay with the use of the osteoclast except in those cases where the curve was close to the joint, when the open operation and chisel were better, because in such cases the osteoclast produced the break too far from the joint.

DR. B. E. MCKENZIE of Toronto said that it was his custom in dealing with bow-legs under three years of age to instruct parents in massage and manipulations, and that 90% of his cases recovered without further treatment.

DR. HENRY LING TAYLOR of New York called attention to the inward rotation in bow-legs and urged that after osteoclasis, outward rotation should be made to overcome this tendency.

DR. JOHN RIDLON of Chicago said that in his experience it was unnecessary to do a tenotomy of the tendo-Achilles in cases of anterior curvature. He had always been able to overcome the deformity after the bones were broken by manual effort. In some cases of bow-legs he thought there might be some tendency to out-grow the deformity, but certainly cases where it had occurred were rare.

DR. PHIL. HOFFMAN of St. Louis reported the findings in a number of radiographs taken of cases of knock knees. He had always observed a bowing-in of the upper end of the tibia and occasionally of the lower end of the femur.

DR. FRANK E. PECKHAM of Providence thought that spontaneous cures in bow-legs had taken place in a number of cases under his observation. Some of them were of a severe type. Tenotomy of the tendo-Achilles was regarded as unnecessary in cases of anterior curvature.

DR. BLANCHARD, in closing, contended that the question of tenotomy in anterior curvature was largely a question of physical strength on the part of the operator. Aside from this consideration, he thought

the foot could be held in better position after tenotomy. In early cases spontaneous recovery might take place except in cases with eburnation of bone, when recovery would be impossible. Manipulation and massage by the mothers were largely responsible for many of the so-called spontaneous cures. In over one thousand cases non-union had not occurred in a single case, and must be extremely rare in this country. Another point made was that in the abduction of the femur there was a change in the position and direction of the neck not necessarily coxa vara. The neck of the femur might be nearly horizontal when the femur abducted, but when the femora were parallel, the position of the necks would be found normal. This might be called simulated coxa vara. True coxa vara is associated with bow-legs, but less often than is apparently the case.

DR. DANE believed that there were natural corrective tendencies in some cases and had observed a number that did make recoveries without formal treatment. He emphasized his belief that bow-legs should be considered as essentially an inward and not an outward bowing.

CONCLUSIONS DRAWN FROM A COMPARATIVE STUDY OF THE FEET OF BAREFOOTED AND SHOE-WEARING PEOPLES.

DR. PHIL. HOFFMAN of St. Louis gave at length the results of a study of one hundred and eighty-six pair of primitive feet, for the most part Filipinos and native Africans. Also a study of the feet of shoe-wearing Caucasians and negroes. As a result of this study, the following conclusions were drawn: The relative lengths of the foot and its component parts are the same in barefooted and shoe-wearing races. Its form and function are the same up to the time of shoe-wearing, after which characteristic deformation and inhibition of function ensue. These acquired characteristics are not transmitted to progeny. The naked foot presents peculiar plantar and dorsal skin markings due to function. The height and shape of the longitudinal arch have no bearing on the strength or usefulness of the foot, unless existent lowness in an individual is a transition from an originally higher state. There is no exclusive type of arch, as the normal, which includes high, medium and low. There is no relationship between the height of the arch and the character of the gait. While the straight position of the foot is the one generally found among primitive people, the everted position is also found. The normal position of the great toe is one in which a prolongation of its axis passes through the center of the heel. A few years of shoe-wearing, as shown by certain African tribes who adopted shoes after the Boer war, suffices to induce deformity. Such compression of the feet as is necessary to produce deformity may be entirely painless.

DISCUSSION.

DR. F. HALSTED MYERS of New York believed that the statement made that the height of the arch and general shape of the foot was not a measure of symptoms was equally true as applied to shoe-wearing races.

DR. JOHN RIDLON of Chicago said that all painful conditions of the foot relieved by the use of an arch supporter could not properly be regarded as cases of flat feet. Such symptoms might arise from a lack of normal dorsal flexion due to a shortening of the calf muscles or what Shaffer calls a non-deforming club-foot.

Discussion also by DR. H. L. TAYLOR, New York, and DR. A. H. FRIEBERG, Cincinnati.

CONGENITAL ABSENCE OF THE TIBIA.

DR. F. HALSTED MYERS of New York reported this condition occurring in boy, aged two. The head of the fibula articulated loosely with the upper and posterior part of the external condyle of the femur, with the foot in marked equino-varus. The leg was habitually flexed and adducted, with slight power of flexion and extension. The child was not able to walk and went about on its knees. At the time the case was first seen there had already been performed a tenotomy of tendo-Achilles with the application of plaster splints without improvement. The fibula was transplanted by the author, necessitating certain interference with the soft structures around the joint. Arthrodesis was performed at the ankle. After one year the boy could flex his leg 90° and almost fully extend it. His power increased rapidly and he walked about all day. A review of the literature showed congenital absence of the tibia to be the rarest of congenital defects. Only forty-six cases of partial or entire absence of this bone were found. In older children it had been regarded as an almost helpless condition. Usually amputation was done on account of great instability of the joint and progressive shortening.

THE DESIRABILITY OF REPLACING CONGENITAL HIP DISLOCATION IN INFANCY.

DR. BERNARD BARTOW of Buffalo contended that the ease of reduction and percentage of anatomical cures increase as the operation is performed more closely to the age when the child should walk. The present lower age limit is arbitrarily placed between the second and third years. Objection to further approximation of the reduction maneuver to the infantile age is based on the difficulty of maintaining cleanliness of the retention dressings. He believed that sufficient importance was not attached to changes occurring in the head and soft parts during the two or three years following birth. These were elements which increased resistance to reduction and diminished the security of replacement and the opportunity for anatomic restoration, compared with the lesser pathological changes present at the walking age. The difficulty of caring for a child at the walking age was not thought to be a barrier to lowering the age limit. A shorter period of splint retention is necessary and there is probably an increased percentage of anatomic restorations. The cast may be extensively cut away on the lateral and posterior thigh portions, leaving a bridge about three inches wide connecting the pelvic girdle with a girdle encasing the lower third of the thigh. No deficiency of support seemed to follow. Several cases were reported showing a period of splint restraint shorter by three or four months than could have been safely contemplated at the age of two or two and one-half years. In five unilateral cases where treatment was begun prior to the second year, anatomic cure was obtained in all. Four of these cases were sixteen months of age or younger.

A STUDY OF THE ANATOMY OF CONGENITAL DISLOCATION OF THE HIP AFTER MANIPULATIVE REDUCTION.

DR. NATHANIEL ALLISON of St. Louis, by invitation, presented a study of a typical case of double congenital dislocation of the hip occurring in a girl of seven, reduced by the Lorenz method. Four months after operation the child died of tuberculous meningitis and the pelvis was obtained at autopsy. The specimen was carefully studied as to the condition of the muscles, nerves, joint capsule, acetabulum and head of the femur. The strength and shortness of the iliofemoral band was such as offered an absolute resistance to a return of the hip to a normal position. Forcing extension would have resulted in dislocation. The head

of the femur was conical and the neck abnormal. The acetabulum was shallow, triangular in shape, with the base posterior. The writer then made a comparison of the anatomical conditions found in this and other so far reported cases.

DISCUSSION.

DR. JOHN RIDGEL of Chicago said that theoretically he agreed with Dr. Bartow in his contentions, but practically he could not. He had had experience in one case seventeen months old and it was such that he at that time decided never to operate upon so young a child again. He believed it to be the experience of those who had operated upon cases under two years of age that while reduction might be more easily accomplished, it was more difficult to retain the head in position. The older cases, offering difficulties to reduction, oftentimes when once reduced stay securely in position. He believed, on the contrary, that the older cases did not require as long a period of immobilization. The younger cases, after eight or ten months in plaster, the head still slips out of the acetabulum. He thought it likely that other muscles besides the adductors acted as stays to keep the head in place, and that this retentive force is absent in young children. In conclusion, he said that he did not yet know what factors lead up to a perfect anatomical result.

DR. H. AUGUSTUS WILSON of Philadelphia said that while upon a theoretical consideration it might appear that early replacement was desirable, the fact remained that in the inability of the child to walk, an important factor in the production of good final results was lost. No two cases are alike and the procedure adopted should depend upon a study of the individual characteristics of each case. He had used a solution of rubber to coat the cast and make it waterproof as recommended by Hoffa, and found it satisfactory in protecting the cast from moisture.

DR. BARTOW, in closing, said that his cases were too few in number to establish a precedent. His experience, however, had not led him to the same conclusions as those gentlemen who had discussed his paper.

SECOND DAY, WEDNESDAY, JUNE 7, 1905.

DR. E. H. BARTOW of Boston gave a clinical demonstration of the pathology and methods of treatment of congenital dislocation of the hip at the Children's Hospital, with an exhibition and demonstration of a machine for reducing congenital dislocation of the hip, by Mr. R. W. Bartlett of Boston.

DEMONSTRATION AND EXHIBITION BY LANTERN SLIDES OF LESIONS IN NON-TUBERCULOUS ARTHRITIS.

DR. I. H. NICHOLS of Boston, by invitation, gave this demonstration of the changes undergone by the bones, joints and cartilages in chronic non-tuberculous arthritis, showing the processes of thickening, erosion, fibrillation, ossification, and the formation of joint mice and osteophytes. A tentative classification, based upon the pathology was suggested and it was pointed out that a satisfactory clinical classification was not possible.

SKELIOTOMIC DEMONSTRATION OF LONG CHANGES IN OSTEOARTHRITIS.

DR. E. A. WELCH of Rochester gave this demonstration and showed a number of skeliotomic and osteoarthritic conditions in various stages.

DISCUSSION.

DR. REGINALD H. SEYMOUR of New York said that a number of different conditions had been met with in the same pathological process, and that the

number of processes called by the same name. Probably a number of etiological factors were to be assigned. Much was yet to be learned of the condition. He wished to urge the importance of mechanical treatment in these conditions. It seemed to him that the process was to be regarded as essentially an inflammation, sometimes of the subacute variety, with distinct indications for local protection of the joint. This idea seemed to have been lost sight of by orthopedic men. A number of cases were reported in which the application of a splint had relieved the pain, increased motion and apparently stopped the process.

Dr. G. C. DAVIS of Philadelphia thought that an endeavor should be made to prevent the deformity. Fixation should be used not only for protection and the alleviation of the immediate symptoms, but for the prevention of deformity. Another point was the question of obtaining motion in such joints. Passive movements might be used to break up adhesions under ether, but in his experience they reformed with greater involvement. Considerable might oftentimes be done by the use of an apparatus as a pendulum which would "jog" the joint to an extent not sufficient to produce severe or lasting pain. This method he believed could be applied with good results to the small joints of hand and fingers and perhaps also of the elbow, wrist and knee.

Dr. J. E. GOLDTHWAIT of Boston believed that when the subject was studied further, the difficulty of satisfactorily classifying the different conditions would disappear. Some of the types now recognized would later come to be recognized as stages of the same process. He had found infection of low grade associated with a number of cases with fringe formation in the joints and believed this to be one of the causes of fringe formation.

Dr. NICHOLS, in closing, said he thought it better to attempt to make a diagnosis of a certain condition rather than a particular disease. He believed that the same cause might result in a varying number of processes. A patient with a number of affected joints might present all the types, so-called. As to treatment, many of the cases were considered hopeless because of extensive destruction in so far as restoration was concerned. In the early cases, protection, fixation, baking and passive congestion might give nature a chance to effect a cure; those of infectious nature with organisms of low grade, opening and drainage. In cases with erosion and chondrification, excision while resulting in a fixed joint might relieve the pain.

A REPORT ON THE ADULT WARD FOR WOMEN IN THE HOSPITAL FOR RUPTURED AND CRIPPLED FOR TWO YEARS, ENDING MARCH 1, 1905.

Dr. V. P. GIBNEY of New York made this report, detailing the number and character of conditions with the immediate and final result indicated in each case so far as possible. The method of treatment was given. He spoke of the great advance made in adult orthopedic work in New York. The ages of the patients varied from fifteen to sixty-seven, covering a wide range of conditions.

CONCERNING PATTERNS OF THE SPINAL CURVE OF PATIENTS WITH PLASTER JACKETS FOR POTT'S DISEASE. HOW THESE MAY BE USED WITHOUT DISTURBING THE JACKET TO DETECT SLIGHT CHANGES OF THE CURVATURE.

Dr. AUG. THORNDIKE of Boston presented this paper together with the apparatus used for the estimation of the kyphosis. It was designed to detect

recurrence of deformity, as it affords the means of making careful measures from time to time. If progress of the case was by this means found to be unsatisfactory, the application of a new jacket would be indicated. If recovery progressed properly, unnecessary disturbance could be avoided. The use of a modified "hammock" method of applying jackets had been found most satisfactory and was described in the paper.

AFTERNOON SESSION.

After an inspection of the building, work and methods of the Industrial School for Crippled and Deformed Children, the afternoon program was taken up in the school building.

RIGID SPINE: A STUDY WITH A REPORT OF FIVE CASES. AUTOPSY.

Dr. GEO. R. ELLIOTT of New York, in a paper of this title, reported two cases of rigid spine of the Strumpell-Marin type, in one of which an autopsy report was given with exhibition of the vertebral column. Another case was of the so-called Bechterew type. A new classification was presented for consideration, in the belief that the one in use was unsatisfactory because of grouping entirely different conditions under one head. It was urged that more careful investigations of the pathology and clinical aspects be made.

DISCUSSION.

Dr. J. E. GOLDTHWAIT of Boston believed that the traumatic cases of rigid spine were in reality cases of arthritis deformans with the trauma as an exciting factor. He thought the reason for the referred pains — intercostal neuralgias and neuralgias of the arms and legs — were very readily explained by the pressure in the foramina. In those cases in which the hypertrophic change took place in the laminae of the dorsal region, the costo-vertebral articulations were involved with ankylosis, so that thoracic movement was limited. In such cases the prognosis would be less good.

COXA VARA ADOLESCENTUM AND OSTEO-ARTHRITIS DEFORMANS COXA.

Dr. A. H. FRIEBERG of Cincinnati said that investigation of the subject had revolved the condition of bending of the femoral neck into a number of components depending upon a number of morbid processes. Mayol (1897) called attention to the fact that osteoarthritis deformans occurs in juvenile form and simulates non-symptomatic coxa vara. Pathological investigation has shown this condition to be far from rare in youth, requiring it to be taken into account more carefully in the differential diagnosis of coxa vara. The contention that the juvenile form is always traumatic is no longer tenable. Two cases were reported in which this condition came on after adolescence with symptoms precisely those of essential coxa vara. The differential diagnosis was made only by the x-ray, which showed the process to be one of yielding of the femoral neck. The importance of differential diagnosis in reference to treatment and ultimate prognosis was insisted upon.

DISCUSSION.

Dr. J. E. GOLDTHWAIT of Boston said that he had seen a similar case to those reported with bilateral involvement in which an osteotomy was deemed inadvisable.

Dr. REGINALD H. SAYRE of New York reported a case which he had seen showing symptoms of unilateral incipient hip disease. X-ray demonstration showed

the head and neck porous, a condition which must have existed for some time before the development of symptoms. No deformity had taken place, but doubtless would have resulted in a short time. A splint was applied to take the weight of the body from that leg.

FRACTURE OF THE CERVICAL SPINE.

DR. REGINALD H. SAYRE of New York, in discussing this subject, reported a number of cases in which a satisfactory result had been obtained, showing the condition not to be necessarily fatal. The deformity produced by the condition resembled wry-neck. Treatment consisted of rest in bed, the application of a jury mast and plaster jacket extending over the head and neck. In cases where the patients have been allowed to stand upright too soon without support to the head, the paralysis which accompanies nearly every case has returned. If the fracture does not unite completely, pressure paralysis will be caused in the arms and sometimes in the legs through change in the relation of the fragments. These symptoms can often be removed by supporting the head and by degrees restoring the relations of the parts more nearly to the normal. In a certain number of cases, support can be dispensed with after a time without the recurrence of paralysis. In some cases operative interference is necessary to obtain a cure.

PERIARTHRITIS OF THE SHOULDER. REPORTING EIGHT CASES.

DR. HOMER GIBNEY of New York, by invitation, reported eight cases of periartthritis of the shoulder, six of which were the result of a fall. In three the diagnosis of rheumatism was made, in one a contusion, and others showed evidence of general involvement of the joints. Treatment consisted in breaking up adhesions under ether, after which hot compresses applied, massage, Paquin thermo-cautery. A circumflex neuritis was thought to have been associated with the condition.

MULTIPLE OSTEOMA.

DR. G. G. DAVIS of Philadelphia reported two cases of multiple osteoma. One occurred in a man fifty-three years of age, who gave no history of a similar affection in any other member of his family or relations. Trouble began at twelve without an apparent traumatism as a cause. The deformities were of the type of both exostosis and osteophytes, generally distributed over the body.

The other case occurred in a child and were extensively distributed over the body. The facial bones were not enlarged in either case, although in the second case there was heading of the ribs and enlargement of the epiphyses, with funnel breast. Syphilis was excluded as a cause in either case.

DISCUSSION.

DR. HENRY LING TAYLOR of New York reported the occurrence of a similar condition occurring in three children, brothers and sisters, ranging from six to fourteen years of age, all seriously affected with gradually growing, painful tumors producing deformity. There was not a similar affection in the mother, but the father complained of considerable stiffness in the joints.

DR. H. P. H. GALLOWAY of Toronto had seen a similar case, eighteen years of age. The trouble first began at nine years of age with growth upon the bones of the feet and near the shoulder. These were removed and did not return, but other enlargements appeared in

large number over the body. They were painless except two that caused pain on sitting. These were removed with very great ease. Most of the growths were near the epiphyseal lines.

DR. A. H. FRIEDBERG of Cincinnati reported a case in which a similar affection had existed for three generations. The patient was a boy of eighteen who submitted to operation for an aneurism, caused by one of the growths in the popliteal space. The growths were situated near the joints in such a way as to mechanically interfere with free motion.

DR. DEXTER D. ASHLEY had seen an instance where the affection had run through four successive generations of the same family.

DR. L. A. WEIGEL did not consider that all such cases should be regarded as asseomata, but rather gave evidence of being a general disease of the osseous system and not a localized disease.

THIRD DAY, THURSDAY, JUNE 8, 1905.

DR. J. E. GOLDTHWAIT and DR. C. F. PAINTER of Boston gave a clinical demonstration at the Massachusetts General Hospital, of cases illustrative of the various forms of bone and joint disease met with in adults, with an operation on the knee joint. Also several cases of osteo-arthritis of the spine and hip and several cases of injury and disease of the pelvic articulations were shown.

DR. E. A. CODMAN of Boston by invitation, gave a demonstration of the surgical anatomy of periartthritis of the shoulder joint.

AN ANALYSIS OF 152 CASES OF HALLUX VALGUS IN 77 PATIENTS, WITH A REPORT UPON A NEW OPERATION FOR ITS RELIEF.

DR. H. AUGUSTUS WILSON of Philadelphia considered improperly shaped shoes and stockings as a frequent cause of hallux valgus. The most potent etiological factor was considered to be eversion and pronation of the feet. It was further stated that hallux valgus was usually synonymous with bunion but either might occur separately. The condition was found to exist in about 20% of 397 women examined for the condition. It was said to occur much more frequently in women. Apparent exostases existed clinically in about 92% of the cases. Radiographic examination show a much lesser number of exostases and showed the inner aspect of the distal extremity of the metatarsal at bone protruding in such a way as to clinically simulate a true exostosis. Pronation of the feet was shown in 80% of the cases and eversion present to a slightly greater extent, causing the final propulsive spring of the foot to fall upon the bunion joint further increasing and aggravating the condition. In 23% of the cases flat-foot was associated condition. There were found in addition widening of the space between the first and second metatarsal bones with oftentimes a curve in the length of the first metatarsal, displacement of the first phalanx of the great toe with angular deformity, hypertrophic enlargement of the head of the metatarsal bone. The operation consisted in removing the projecting portion of metatarsal bone, after excision of bursa, and placement of the toe in the reversed divergent position, passive movements in two weeks and resumption of walking in three. Results were entirely satisfactory in cases reported.

DISCUSSION.

DR. JAMES K. YOUNG of Philadelphia said that in such cases requiring bone operations he made use of a linear osteotomy performed just back of the bunion and the results achieved were entirely satisfactory.

DR. NEWTON M. SHAFFER of New York had had good success in the treatment of a certain number of cases of hallux valgus caused, he believed, by shortening of the gastrocnemius by the application of a traction shoe.

DR. HENRY LING TAYLOR had formerly taken an oblique bite from the inner condyle, but had gradually increased the amount of bone removed until the entire head removed by means of ordinary transverse bite. Some motion was left and the damage to the arches of the foot was considered inconsiderable.

DR. CHARLES F. PAINTER of Boston said that he believed that a considerable number of cases could be cured without operation by restoring proper static conditions of the foot and the use of proper shoes and stockings. Exostoses were considered as irritative in origin. Mueller's operation had given good results, and he did not consider the objections that had been urged against it valid.

DR. REGINALD H. SAYRE had seen a case in which reduction of the deformity accompanied by a loud snap has resulted from adduction of the toe. He thought possibly some operation might be devised by which cutting of soft structures would cause reduction of deformity.

DEMONSTRATION OF MACHINE FOR CORRECTION OF DEFORMITIES AT THE HIP FOLLOWING HIP DISEASE AND FOR HOLDING THE LIMB IN CORRECTED POSITION WHILE PLASTER IS APPLIED.

DR. JOHN RIDLON of Chicago exhibited the machine and gave a demonstration of its use.

ACHILLOTOMY AND FASCIOTOMY IN A PATIENT SEVENTY-TWO YEARS OF AGE.

DR. A. R. SHANDS of Washington reported a tenotomy and fasciotomy upon a patient of seventy-two for the relief of equino-varus, the result of poliomyelitis. The operation was performed under cocaine, and plaster applied for three weeks. The result was entirely satisfactory and the patient could walk with ease and comfort.

DISCUSSION.

DR. FRANK E. PECKHAM of Providence had performed a tenotomy upon a patient of seventy, with good union following.

DR. PHIL. HOFFMAN of St. Louis had performed a tenotomy upon a patient aged forty-five years of age in the endeavor to relieve a contracture, the result of infantile paralysis. Twelve days later an amputation was necessary. Examination showed good union taking place in a limb devoid of muscular fibres and made up of muscle sheaths, fat and connective tissues.

INVESTIGATIONS ON THE VALUE OF TRACTION IN THE TREATMENT OF HIP DISEASE.

DR. E. H. BRADFORD of Boston in his paper said that although the advantages of traction in the treatment of hip disease had been abundantly shown, the benefits to be derived had been questioned by some writers, and that a further demonstration of the value of this method would be of use. It may be assumed that bone affected by tubercular osteitis may, under favorable conditions, be transformed into a healthy state, and that constant irritation and bruising of the diseased portion of the bony structure is unfavorable in repair and cure. An examination of a number of specimens of advanced hip disease showed indisputably the forcible crowding of the head of the femur upwards and backwards, leaving the lower portion of the acetabulum opportunity for early repair. Corresponding changes had taken place in the head of the femur.

It was manifestly desirable in placing the bone in a condition favorable to repair that this crowding should be prevented. By a series of skiagrams taken of patients suffering from hip disease and subjected to various degrees of traction, it had been demonstrated that traction could be used so as to prevent this crowding. Distraction caused by traction should vary in the different stages of hip disease.

DISCUSSION.

DR. PHIL. HOFFMAN of St. Louis said that he had a specimen obtained from a boy suffering from hip disease, who died of meningitis, that showed very well the crowding of the joint. The bone disease was located in the epiphysis and pus had just broken into the joint, although microscopically and macroscopically there was no evidence of tuberculous involvement of the joint, yet there was a decided flattening of the cartilages with a wearing away of the joint surfaces.

DR. R. H. SAYRE of New York was firmly convinced of the value of traction, not only in hip cases, but in knee and ankle cases as well.

DR. NEWTON M. SHAFFER of New York pointed out how closely the ideas set forth in the paper corresponded with the principles of C. F. Taylor years before, who had based his treatment, not upon a knowledge of the pathology, but upon empiricism.

DR. C. W. WILSON of Montreal said that notwithstanding the arguments which had personally been urged upon him by distinguished foreign orthopedists, he was convinced of the value of traction and continued to use it.

A STUDY OF THIRTY CASES OF CHRONIC NON-TUBERCULOUS JOINT DISEASE OCCURRING IN ADULTS, WITH SPECIAL REFERENCE TO SOME OF DOUBTFUL IDENTITY.

DR. HAROLD W. JONES of St. Louis, by invitation, read a paper in which a study was made of non-articular joint lesions of non-tuberculous origin, involving the ankle, knee, hip, shoulder, elbow and spine. Syphilis was the etiological factor in one case and gonorrhea in three others. The cases were divided as follows: (1) Cases characterized principally by hypertrophy of the joint. Seven cases were included in this group. (2) Cases characterized principally by atrophy of the joint. One case was included in this group. (3) Cases of undoubted infection, in some of which erosion of the articular surfaces was demonstrated. There were five cases in this group. (4) Cases of probable peri-arthritis, in which infection was at least uncertain and which no permanent changes in the joint could be shown. In this latter group seventeen cases were included. In the entire series osseous hypertrophy occurred entirely in the male sex and in the weight-bearing joints. Exposure to sudden changes of temperature and occupation trauma were not found to be an important etiological factor, except in the shoulder, often the seat of disabling joint lesions, where trauma was regarded as an important factor. Moderate success only was achieved in the treatment of the cases.

A FRAME FOR HOLDING A PATIENT WITH A FRACTURE OF THE SHAFT OF THE FEMUR WHILE PLASTER-OF-PARIS IS APPLIED.

DR. FRANK E. PECKHAM of Providence described a frame designed to support the body and make extension with sufficient force to pull the leg down to length and hold it there firmly until the plaster is applied and completely set. The plaster should take in the whole body, from the axillae down to and including the fractured leg.

A MODIFICATION OF THE DOLLINGER BRACE FOR CERVICAL AND UPPER DORSAL, POTT'S DISEASE.

DR. R. T. TAYLOR of Baltimore described a brace to be used in Pott's disease, which was claimed to be rigid, durable and light. The brace was made from plaster-of-Paris bandages braced with steel from a corrected cast of the back and head.

A MODIFICATION OF THE BACK BRACE FOR POTT'S DISEASE.

DR. AUG. THORNDIKE exhibited a brace designed to obtain uniform pressure over the line of the transverse processes undisturbed by body movements. The neck piece was eliminated and the lung capacity increased by keeping the shoulders back and elevating the ribs by the action of the serratus muscles.

PLACE OF MEETING AND ELECTION OF OFFICERS.

The Association adjourned to meet in annual session in Toronto, Canada, at such time as would be set by the Executive Committee. The following officers were unanimously elected to serve for the ensuing year: President, Dr. B. F. McKenzie of Toronto; first vice-president, Dr. C. W. Wilson of Montreal; second vice-president, Dr. H. P. H. Galloway of Toronto; secretary, Dr. John Dillon of Chicago, re-elected; treasurer, Dr. E. G. Brackett of Boston.

Recent Literature.

A Treatise on Diagnostic Methods of Examination. By PROF. DR. H. SAHLI, of Bern. Edited, with additions, by FRANCIS P. KINNIEUTT, M.D., Professor of Clinical Medicine, Columbia University, New York; and NATHANIEL BOWDITCH POTTER, M.D., Visiting Physician to the City Hospital and to the French Hospital, and Consulting Physician to the Manhattan State Hospital, New York. pp. 1,008. profusely illustrated. Philadelphia and London: W. B. Saunders & Co., 1905.

The translation of a comprehensive foreign work into English is a difficult and often a thankless task. Foreign languages, and particularly German, are sufficiently well understood by many physicians at the present time to permit of immediate reference to the original. There remains, however, a large class of physicians who in spite of general medical attainment have not mastered any foreign language sufficiently to make its use easy. To these persons such a book as the one before us is especially directed, although it will also prove of much value to all but the most expert German scholars. The translation, with certain annotations and occasional added illustrations, has been admirably done by Drs. Francis P. Kinnieutt and N. B. Potter of New York, with the assistance of other collaborators. This volume is a translation of the fourth edition of Professor Sahli's widely known and deservedly popular treatise on diagnostic methods. The book is peculiarly comprehensive in scope and covers the entire field of internal medicine, including the skin, from the general diagnostic standpoint. Although diagnostic method is its professed aim, the author does not hesitate to discuss

pathological and clinical matters in a much more complete way than is ordinarily met with in books of this character. The author insists that his work is not a mere compilation, but rather the expression of personal opinion and experience. He finds fault, and with justice, with the attitude which assumes that a textbook cannot represent an original contribution to medicine and regrets that the journals and periodicals have come to be the sole repositories of medical literature. Unfortunately, the character of many textbooks justifies the popular attitude, but Professor Sahli's admirable work, as many others which have appeared in Germany, are certainly not to be placed in this category. We have no question that the translation will receive wide recognition in this country, as the original has in Europe. It stands as one of the most comprehensive textbooks on diagnostic methods which we have in any language.

A Manual of Chemistry. By ARTHUR P. LUFF, M.D., B.Sc., F.R.C.P., F.I.C., Physician to St. Mary's Hospital, and Lecturer on Medical Jurisprudence in the Medical School; and FREDERIC J. M. PAGE, B.Sc., F.I.C., Lecturer on Chemistry and Physics to the London Hospital Medical College, Examiner on Chemistry and Physics to the Society of Apothecaries, London, Chicago: W. T. Keener & Co., 1905.

The first edition of this manual appeared in 1892 and since then two have been prepared. In this third edition we find a few additions, such as short descriptions of the determinations of the boiling-point and melting-point with the connection between the structure of a substance and its behavior to polarized light. There is also a brief chapter on the composition of some of the substances which have recently come into use as drugs. The work is admirably suited to give a superficial knowledge of both organic and inorganic chemistry.

Lea's Series of Medical Epitomes. Edited by VICTOR C. PRIDGEN, M.D.

Arnall's Epitome of Clinical Diagnosis and Urinalysis. A manual for Students and Practitioners. By JAMES R. ARNALL, A.B., M.D., Professor of Medicine and Clinical Medicine in the University of Colorado, Physician to the County Hospital and to St. Joseph's Hospital, Denver. In one 12mo volume of 244 pages, with 79 engravings and a colored plate. Philadelphia and New York: Lea Brothers & Co., 1905.

A large number of very important subjects are considered in this small volume, but the treatment of each subject is necessarily so brief that it cannot be very valuable. The greater part of the text has been taken from a number of well known works which are still available and well known to date. The intentions of the editor, author and publishers were good, but we feel that it was a mistake to attempt so much in space that

Methods of Organic Analysis. By HENRY C. SHERMAN, Ph.D., Adjunct Professor of Analytical Chemistry in Columbia University. New York: The Macmillan Co. 1905.

In the words of the author, "the purpose of this work is to give a connected introductory training in organic analysis, especially as applied to plant and animal substances and their manufactured products." In the 245 pages of the book we find a substantial consideration of quantitative methods for food materials and related substances, such as nitrogen, sulphur, phosphorus, alcohols, aldehydes, carbohydrates, vegetable and fatty acids, oils, fats, waxes, butter, soaps and lubricants, proteids, and cereals and milk. Most of the portion devoted to aldehydes is given up to the subject of formaldehyde, and we consider this a valuable feature of the work. The book was written primarily for the use of the students in the School of Chemistry at Columbia, but we would favor its adoption by other schools because of its intrinsic worth.

A Textbook of Diseases of Women. By BARTON COOKE HIRST, M.D., Professor of Obstetrics, University of Pennsylvania. Second edition, revised and enlarged. Octavo of 741 pages, with 701 original illustrations, many in colors. Philadelphia and London: W. B. Saunders & Co. 1905.

The second edition of Dr. Hirst's book has been improved by the addition of many new illustrations and a thorough revision of the subject matter. Although there are some sixty additional pages the volume has not reached unwieldy proportions. As a textbook brought up to date it merits all the favorable things we said of the first edition two years ago.

The Channels of Infection in Tuberculosis. Together with the conditions, original or acquired, which render the different tissues vulnerable. Being the Weber-Parkes Prize Essay, 1903. By HUGH WALSHAM, M.A., M.D., F.R.C.P., Physician to Out-Patients, formerly Pathologist to the City of London Hospital for Diseases of the Chest. New York: William Wood & Co. 1905.

The Weber-Parkes Prize is awarded triennially by the Royal College of Physicians of London to the writer of the best essay submitted in competition. The subject selected deals with the etiology, prevention, pathology or treatment of tuberculosis, especially with reference to consumption in man. Dr. Walsham's monograph is of great value. It represents the results of much painstaking work at the autopsy table and at the microscope. While pathologist to the City of London Hospital for Diseases of the Chest, Dr. Walsham made 200 autopsies on subjects of tuberculosis and in every case endeavored to discover the portal of entry of the tubercle bacillus and to trace out the channels of infection.

The importance of this systematic study is shown by the fact that in 26 out of 27 consecutive cases of pulmonary tuberculosis the cervical and bronchial glands were found to be tuberculous. In several cases the infected glands were not enlarged and appeared healthy on naked-eye examination. Detailed notes of the cases are given. From his observations he concludes that the tonsils are frequently affected with tuberculosis. Although the tonsils may be the primary seat of the disease the lesion is usually secondary to pulmonary tuberculosis. In 20 out of 24 consecutive post-mortem examinations the tonsils were found to be tuberculous. In the majority of these cases the tonsils were atrophied.

The second part of the essay is devoted to a consideration of the relations of alcohol and various diseases to tuberculosis. Strong evidence is brought forward to show that tuberculosis of the lungs rarely develops in a case of mitral stenosis. The pulmonary congestion induced by obstruction of the mitral orifice appears to protect the lungs from tubercle bacilli. Pulmonary anemia favors infection. This view is supported by the fact that nearly all cases of pulmonary stenosis die of tuberculosis.

There is throughout the essay reference to the work of other investigators, but the study of the literature has been by no means complete. The book is richly illustrated with 16 colored plates, made from the author's histological specimens. It is printed on thick opaque paper of very light weight, making the volume a convenient one to handle.

The Harvard Medical School. A History, Narrative and Documentary, 1782-1905. By THOMAS FRANCIS HARRINGTON, M.D., Class of 1888. Edited by JAMES GREGORY MUMFORD, M.D., Class of 1888. Illustrated. New York and Chicago: Lewis Publishing Company. 1905.

This work occupies three octavo volumes with a total of 1,650 pages, and was a subscription book. Although by title a history of the Harvard Medical School, its scope is necessarily wider and practically covers, though in less detail, the history of medicine in New England from the founding of the colony of Massachusetts Bay onward. The first volume takes us down to 1827, the second to 1871, and the third to the present year. At the beginning of the first volume is an index of names and subjects and at the end of the third volume an Alumni roll.

The preparation of these volumes has evidently entailed a great deal of labor upon the author and editor, which was in large measure a labor of love. Public records and original documents have been consulted, and private papers, documents and manuscripts as well, and all at first hand. Moreover, the range of subjects, including biographical sketches of individuals, is very large. The work of author and editor is well done; its presentation by the publishers is less satisfactory.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JANUARY 4, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$3.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

THE TUBERCULOSIS SITUATION IN BOSTON.

WITH the interest which the tuberculosis question is exciting everywhere, and particularly in Boston at the present time, it is not surprising that the matter of more adequate accommodations for tuberculous persons in this city should be receiving renewed attention. That the number of beds for treatment of the disease, whether in its chronic or incipient form, is wholly inadequate to the demand, is self-evident. It is also not to be questioned that further provision should be made, particularly for the so-called incurable cases. The fact, however, that the means of hospital treatment have been inadequate has not been wholly disadvantageous. It has led to a large amount of instruction as to methods by which persons living at home may still be provided with fresh air and with the means of treatment and possible cure. It would be most unfortunate were hospital accommodations so complete as to prevent this sort of instruction, an admirable example of which is given in Dr. J. H. Pratt's so-called tuberculosis class.

It is, however, recognized that we need more accommodation than we at present have, though it may well be questioned whether it would be wise to construct a large and expensive hospital for this purpose alone in the present state of the tuberculosis problem. Apart from other possible objections, provision for cases of tuberculosis at the Long Island Hospital has very naturally proved totally inadequate to the demand. The inevitable result has been that, although a detached building is provided for tuberculous patients, the number demanding treatment so

far exceeds the provisions of this building that the general hospital is crowded with patients suffering from tuberculosis, although this was the very situation which the erection of the separate hospital was designed to avert. The current report, however, that statistics have shown Long Island to be a totally unfit place for the treatment of the disease should not forthwith be accepted. The type of patient there received is ordinarily a peculiarly hopeless one to treat. His previous habits of life, and the late stage of the disease at which the patient enters the hospital, are far more responsible for his death than the geographical situation of the institution.

We have no present desire to discuss the question as to whether or not it is desirable to extend the facilities for treating tuberculosis at Long Island. The fact remains that further provision should be made especially for chronic and advanced cases. To meet this demand the sum of \$150,000 was set aside four years ago by the city government, but has hitherto not been used owing to the late Mayor Collins' decided attitude that the amount was too small to start an enterprise of this character. As we have previously said, we do not coincide with this opinion. We are, therefore, gratified to see that Mayor Fitzgerald in his inaugural address again reverts to this sum of \$150,000 and urges that it be used for the purpose for which it was originally appropriated. He very properly points out that the buildings required for the treatment of tuberculosis need not be of expensive construction, and that a beginning may well be made with the money now at the disposal of the city toward meeting the crying demand for further hospital accommodation for consumptives. The Mayor closes his remarks on this subject with the following statement with which we are in entire agreement:

"I believe that this board [unpaid trustees] should proceed at once to select a suitable location for such a hospital, and should make an immediate beginning in providing facilities for treatment. The appropriation of \$150,000 may not be as large as will be required soon after the work of this new department gets under way, but in my opinion it is much better to proceed to do something with this amount than to wait for a larger appropriation. Fortunately, the modern method of treatment is such that very simple and inexpensive buildings can be utilized; the treatment is largely carried on in so-called under tents, the freest possible use of fresh air constituting a vitally important feature of it. Indeed, one of the chief benefits from the establishment of such a tuberculosis hospital is the

educational effect on the community at large, for each patient actually treated brings the knowledge of how to treat the disease at home to an ever-widening circle of friends and acquaintances, who thus become active missionaries in fighting this scourge.

"I pledge the fullest co-operation on the part of the executive in taking energetic and effective action to remedy this present great deficiency in the charitable activities of our city."

THE FOOTBALL QUESTION.

IN the present state of public opinion regarding the game of football it is eminently desirable that all possible facts connected with the game be collected and properly digested before any special action is taken. The vague opinion of spectators or the possibly prejudiced attitude of players and coaches should be most carefully weighed before final conclusions are drawn. The moral and physical aspects of the game each need to be thoroughly and impartially investigated; general impressions in this as in other matters of public importance should be relegated to a wholly secondary position. Furthermore, we fortunately have the opportunity for exact observation, the results of which should be made public property.

In this issue of the JOURNAL we publish, so far as we are aware, the first scientific statement of the character, extent and treatment of injuries received on the football field. Dr. Nichols and Dr. Smith have been, during the past season, respectively, surgeon and assistant surgeon to the Harvard University football squad. It will, therefore, not be questioned that they have had a peculiar opportunity, nor will it be denied, a peculiar fitness for the accurate expression of their opinion. It is also not to be questioned that they have approached their problem in an unprejudiced spirit and have deduced conclusions in accurate accord with their observation. Such work as this cannot fail to be of the greatest possible value to the cause of the game, whether or not it does its share toward leading to its reformation. What the public is demanding, and what it has not before had, is just such an authoritative statement of conditions as Drs. Smith and Nichols have given in this carefully prepared report. The meetings of Rules Committees and conferences in general in order to approach the subject intelligently must give due weight to reports such as the writers have presented.

The conclusions reached are perfectly definite and may well provide food for reflection. It is shown that the number and severity of injuries

is much greater than ordinarily believed; that the injuries are inherent in the game itself; that many of the injuries are unavoidable; that the percentage of injuries is very much greater in football than in any other major sport; that the game does not develop the best physical type of man, and that constant medical supervision is not a luxury, but a necessity. However such statements may be interpreted by those taking various views of the game, it cannot be doubted that they express facts and not surmises. Acknowledging these facts, it remains for the authorities to determine whether the advantages of the game as now played compensate for the situation as outlined by Drs. Nichols and Smith. It is, in any case, futile in the future to say that the injuries are trivial and the danger slight. It is also evidently a mistake to suppose that the older and more experienced players are exempt from injury as compared with the schoolboy contingent. We commend most cordially this exhaustive paper to those interested in a game which deservedly or not has become more popular than any other single outdoor sport.

CHARITABLE BEQUESTS OF A YEAR.

WHATEVER the evils of accumulating great wealth may be, its advantages should not be overlooked. It is reported that \$66,000,000 have been given for worthy charitable purposes during the year just passed, and this amount is behind the record of 1901. Of this amount it is gratifying to note that upwards of \$37,000,000 were given for educational purposes in the broad sense. A detailed report, made by the *Chicago Record-Herald* regarding the disposition of this \$66,000,000, shows that 83 colleges and schools are beneficiaries, of which Leland Stanford University, because of the death of Mrs. Stanford, receives nearly \$5,000,000; Harvard University has been the recipient of \$1,500,000 in addition to \$2,500,000 contributed for a teachers' endowment fund, followed by Yale with about \$100,000 less. After education has thus been provided for, galleries, museums and societies are next on the list, having received something over \$7,000,000. Hospitals, homes and asylums have received upwards of \$5,000,000.

It is interesting to observe the uses to which this large amount of money for charitable purposes has been put. The strong hold which education as a fit object for benefactions has taken on the public mind is amply shown by the foregoing figures. A certain portion of this

\$37,000,000 has been used for the purposes of advancing medical education through endowments of various sorts and through construction of new buildings. It is evidently being more and more recognized that money spent for higher education, whether professional or not, must ultimately conduce to the best interests of the country at large. It is hardly less noteworthy that galleries, museums and similar institutions, which in the broad sense may rightly be regarded as forms of liberal education, come next in the list of benefactions, whereas purely charitable objects, such as hospitals, homes and asylums, are third. Not only are these figures interesting in themselves, but they demonstrate the wisdom with which money is given in this country. The two men who have contributed by far the largest sums to this grand total are Mr. Andrew Carnegie and Mr. John D. Rockefeller, the former having given upwards of \$14,000,000, and the latter more than \$11,500,000.

With these figures before us, and with wealth still increasing, and accumulating in the hands of individuals, it is not to be supposed that any worthy educational scheme will suffer long for lack of funds. Naturally, the demands increase as the possibilities of supply multiply, but it is each year being more and more definitely demonstrated that men of wealth are willing to give liberally if they can be shown the worthiness of the object for which they are called upon to provide.

MEDICAL NOTES.

AMERICAN DERMATOLOGICAL ASSOCIATION OFFICERS.—At the twenty-ninth annual meeting of the American Dermatological Association, held in New York City, Dec. 28, 29 and 30, 1905 the following officers were elected for the ensuing year: President, Dr. M. B. Hartzell of Philadelphia, Pa.; vice-president, Dr. Thomas C. Gilchrist of Baltimore, Md.; secretary and treasurer, Dr. Grover W. Wende of Buffalo, N. Y. The next meeting of the Association will be held in Cleveland, Ohio, in May, 1906.

SOCIETY FOR THE PREVENTION OF PREMATURE BURIAL.—A society has recently been organized having for its object the prevention of premature entombment, burial or cremation. The purposes of this newly constituted society are to secure data regarding the resuscitation of persons apparently dead and prematurely buried and to circulate literature on the general subject. Such organizations tend rather to increase than diminish

a widespread morbid anxiety regarding the question of premature death. It is unfortunate that the public should be further distressed in this matter.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.—For the week ending at noon, Jan. 3, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 45, scarlatina 33, typhoid fever 5, measles 54, tuberculosis 25, smallpox 0.

The death-rate of the reported deaths for the week ending Jan. 3, 1906, was 20.42.

BOSTON MORTALITY STATISTICS.—The total number of deaths reported to the Board of Health for the week ending Saturday, Dec. 30, 1905, was 213, against 169 the corresponding week of last year, showing a increase of 44 deaths and making the death-rate for the week 18.67. Of this number 117 were males and 96 were females; 208 were white and 5 colored; 120 were born in the United States, 85 in foreign countries and 8 unknown; 33 were of American parentage, 153 of foreign parentage and 27 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 50 cases and 2 deaths; scarlatina, 16 cases and 2 deaths; typhoid fever, 15 cases and no deaths; measles, 153 cases and 4 deaths; tuberculosis, 31 cases and 23 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 42, whooping cough 0, heart disease 25, bronchitis 10 and marasmus 1. There were 11 deaths from violent causes. The number of children who died under one year was 15; the number under five years, 65. The number of persons who died over sixty years of age was 47. The deaths in public institutions were 62.

NEW YORK.

REAPPOINTMENT OF DR. DARLINGTON.—The reappointment of Dr. Darlington by Mayor McClellan to the position of Health Commissioner has been received with much satisfaction by the medical profession as it is felt that the wisdom of bestowing this important office upon a competent physician rather than a layman has now been demonstrated, and that the present incumbent has performed the arduous duties of the position in an entirely satisfactory manner.

HOSPITAL SATURDAY AND SUNDAY ASSOCIATION.—Favorable weather on the days of the annual collection of the Hospital Saturday and Sunday Association (Dec. 30 and 31) gave prom-

ise of large contributions in the synagogues and churches. During the past year the institutions belonging to the Association, forty in number, cared for 52,713 bed patients, of whom 33,774 were free cases, and treated 314,838 dispensary patients. The total expenses for this work were \$2,450,517, of which \$1,383,286 was provided for by the income of investments, the returns from pay patients, and the appropriations from the city; leaving a balance of \$1,067,231 to come from the benevolent public.

SETTLEMENT OF A DISPUTED WILL. — A noted will case has just been terminated in the New York Supreme Court, the contest being over the estate valued at more than \$2,000,000, of Wallace C. Andrews, who, with his wife, was burned to death in his residence on 67th Street, near Fifth Avenue, on April 7, 1899. On Dec. 22, Justice Dowling handed down a decision to the effect that, the evidence presented not showing whether Mr. Andrews or his wife died first, the will is upheld. By the terms of the will, Mrs. Andrews, should she survive him, was to have a life interest in his estate. On her death the property was to go to the Andrews Institute for Girls, founded by him, in Ohio. Should she die before him, the estate was to go immediately to that institution. The fight over the Andrews estate was a four-cornered one, the executor, the Andrews Institute, the Smithsonian Institution and the relatives of the decedent being separate parties to the suit. The will has a provision that if the bequest to the Andrews Institute should be for any reason illegal or impossible, the estate should go to the Smithsonian Institution. The executor joined issue with the attorneys for the Andrews Institute, and the heirs with the Smithsonian Institution, although the entire estate would presumably go to the latter, by the terms of the will, if the bequest to the Andrews Institute were declared illegal. In regard to the latter point, the Court held that the will cannot be attached in the State of New York, as the Institute is an Ohio corporation.

REPORT OF THE HEALTH DEPARTMENT. — The condensed report which was made to Mayor McClellan last summer by the Health Department, of the work done by it during the six months ending July 1, 1905, has just been printed and sent out. Among the parts of it which had not previously been made public the following are worthy of note: The work of the Sanitary Police was effective. The number of arrests made was 2,800, as against 1,459 in the first six months of

1903, and 2,110 in the same period in 1904. The number of nuisances abated by personal effort were: 1903, 6,956; 1904, 9,686; 1905, 9,054. The portion of the law relating to the employment of women and children in mercantile establishments which comes under the jurisdiction of the Health Department has been efficiently enforced. Eleven thousand certificates were issued, and 2,600 applications rejected. Thirteen thousand mercantile establishments were inspected, and very few cases of persistent disobedience of the law, requiring drastic action, were found. The work of medical inspection and the subsequent care of nurses, and the physical examination in the public schools, was vigorously prosecuted. The figures show that while in the first six months of 1903 no less than 51,664 children were excluded from school, in the same period of 1905 only 10,585 were excluded, — an enormous educational saving. Many minor diseases which were formerly excluded are now treated in the schools. Dr. Darlington thinks that the present system, which has proved so efficient in the schools in which it has been employed, should be extended to all the schools of the city. This work is, in his opinion, of as great importance as any which has ever been undertaken by the New York Health Department. It is gratifying to note that there was an increase in births and marriages reported, and a decrease in deaths, in every borough. There were 50,943 births reported, in comparison with 47,384 during the first six months of 1904. There were 20,768 marriages, as compared with 19,295 in 1904; and 37,969 deaths, as compared with 42,690 in 1904, reducing the death-rate from 22.24 to 19.23.

--- **Miscellany.**

LECTURES ON PNEUMONIA AND CEREBRO-SPINAL MENINGITIS.

On Dec. 29, Dr. Darlington gave the first of a series of public lectures which has been inaugurated by the New York Academy of Medicine, and it was devoted mainly to the subjects of pneumonia and cerebrospinal meningitis. In the course of it he said, after giving a number of statistics: "A fair conclusion is that the recent apparent increase of pneumonia has been mainly due to the transfer of part of the bronchitis mortality record to the pneumonia record, either as a matter of classification by registrars or of diagnosis by physicians, or both. While the figures do not bear out the belief that pneumonia is on the increase — showing, in fact, just the contrary to be true — we must remember that the general death-rate for all diseases has

decreased by about one fourth. The decrease in pneumonia, therefore, has not kept pace with the general improvement in the health of the inhabitants." He then gave the results of a study of 321 cases of pneumonia in New York, in December, 1901, and January, 1905. Among these there were 56 deaths; 7 in persons under fifteen years old, 31 in the ages between fifteen and fifty, and 18 in persons over fifty. The average mortality rate was 20.5%. Dr. Darlington gave a summary of the results obtained by the Health Department commissions on both pneumonia and meningitis. The conclusions of the latter commission he announced as follows:

(1) The disease has occurred in several large epidemics during the past century; sporadic cases are met with in the periods between these epidemics and constitute the link between them. We do not know the circumstances giving rise to these epidemic outbreaks.

(2) The epidemic form of cerebrospinal meningitis is almost invariably associated with the meningococcus of Weichselbaum, and the sporadic cases are frequently associated with the organism. During the first week of the disease this organism is present in the nasal mucus in fully half the cases; later in the disease it is found in a smaller fraction. It also occurs in the nasal mucus of some persons who are in close contact with cases of the disease. The meningococcus is of low vitality, and is rapidly killed by drying and on exposure to sunlight. This makes infection by dust extremely improbable.

(3) The disease seems distinctly communicable in the sense that the organism is transmitted from the nasal secretion of one person to another. The transmission of the organism, however, is not synonymous with the transmission of the disease. The disease in some epidemics affects mostly infants, in others, older children, and sometimes chiefly adults. The reason for this is not at all clear.

(4) It seems unlikely that infection is frequently due to trauma or the result of over-exertion. Cerebrospinal meningitis in animals seems to have no connection with the disease in men. There is no evidence to show that the disease is carried by vermin or insects.

(5) The susceptibility of the individual is an important factor in the development of the disease.

(6) The period of incubation is short, from one to four days.

(7) There is no evidence of the occurrence of a dwelling infection.

(8) It would seem well to isolate most cases of cerebrospinal meningitis occurring in the crowded tenement districts.

In the report there were, apparently, no recommendations or suggestions as to treatment. In the epidemic in New York last winter and spring Dr. Darlington said that out of 365 cases reported there were 344 deaths—a mortality of 91%. All the cases of the disease were carefully indexed and arranged according to sections and

streets. In a group of 58 instances in which more than one case occurred in a house, representing 141 cases in all, the following results were shown: In 39 instances, 2 cases to a house; in 15 instances, 3 cases to a house; in 2 instances, 4 cases to a house; in 1 instance, 5 cases to a house; in 1 instance, 8 cases to a house. In three of these instances the disease occurred in the families of janitors, appearing to have been communicated to or by them in the ordinary intercourse with the tenants. In two instances the disease appeared to have been contracted in school.

IMMUNIZATION OF COWS AGAINST TUBERCULOSIS.

The Paris correspondent of the *British Medical Journal* writes that: "The experiments which have been conducted during the present year at Melun, in the department of Seine-et-Marne, to render cows immune to tubercle have been successful. On Dec. 3 a certain number of bacteriologists and veterinary surgeons assembled in the stables of the old barracks to verify the results. On Feb. 19 last a certain number of animals—Dutch cows, Limousin bulls and Normandy cattle—all young and healthy, were vaccinated with an emulsion extracted by Behring's method from tubercle bacilli by M. Vallé, Professor at the Veterinary School of Alfort. Towards the middle of June the vaccinated animals were divided into three lots: (1) Seven of these and seven healthy unvaccinated cows of the same race and age were all inoculated under the skin of the shoulder with the tuberculous virus; one month later all the control animals showed vast tuberculous lesions, while all the vaccinated beasts were free, with the exception of one or two which showed insignificant traces of the infection. (2) Six vaccinated and six unvaccinated animals had virulent cultures injected into the jugular vein, with a much more marked difference in the results obtained. The six vaccinated animals remained in good health, while all the control animals were gravely affected, three dying in a fortnight. (3) Vaccinated cows were placed alongside tuberculous animals in the same cowshed. The vaccinated animals have resisted, while the control animals on post-mortem examination showed generalized tubercle. MM. Vallé and Moussu, professors at Alfort, intend keeping these animals to prolong the experiment and see how long this immunity will last. M. Vallé gave a lecture explaining the results of the experiments to the assembled company. Immunity has been proved but its duration is as yet unknown. If the vaccination will protect the animal for eighteen months or two years, then the problem may be considered as solved, which will only require a law making vaccination compulsory to protect cattle from infection. M. Roux, of the Pasteur Institute, is to make an examination of the tuberculous lesion in the animals which served as controls to check the experiments."

RECORD OF MORTALITY FOR THE WEEK ENDING SATURDAY, DEC. 16, 1905.

| CITIES. | Population. Census, 1900. | Reported deaths in each. | Percentage of deaths from | | | | |

Deaths reported, 3,149; under five years of age, 853; principal infectious diseases (smallpox, measles, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption), 622; acute lung diseases 605, consumption 329, scarlet fever 14, whooping cough 5, cerebrospinal meningitis 21, smallpox 0, erysipelas 8, puerperal fever 11, measles 31, typhoid fever 45, diarrheal diseases 67, diphtheria and croup 75.

From whooping cough, New York 2, Baltimore 1, Fall River 1, Brockton 1. From scarlet fever, New York 4, Chicago 1, Philadelphia 3, Baltimore 2, New Bedford 3, Brookline 1. From cerebrospinal meningitis, New York 17, Philadelphia 1, Providence 1, Boston 1, Worcester 1. From erysipelas, New York 5, Chicago 5, Philadelphia 1. From typhoid fever, New York 17, Chicago 4, Philadelphia 10, Baltimore 3, Providence 1, Boston 2, Worcester, Lynn, Lawrence, New Bedford, Somerville, Salem, Waltham and Pittsfield 1 each. From measles, New York 5, Chicago 5, Philadelphia 5, Baltimore 1, Boston 3, Lowell 1, New Bedford 11. From diphtheria and croup, New York 20, Chicago 11, Philadelphia 13, Baltimore 1, Providence 2, Boston 2, Quincy 2, New Bedford 9, Fall River, Lowell, Cambridge, Holyoke, Haverhill, Taunton, Everett and Hyde Park 1 each.

In the seventy-six great towns of England and Wales, with

an estimated population of 15,609,377, for the week ending Dec. 9, 1905, the death-rate was 16.1. Acute diseases of the respiratory organs (London) 192, whooping cough 80, diphtheria 52, measles 110, smallpox 0, scarlet fever 55.

The death-rate ranged from 7.0 in Hastings to 25.8 in Bootle; London 16.3, West Ham 11.3, Brighton 10.2, Southampton 20.4, Plymouth 18.4, Bristol 14.7, Birmingham 18.2, Leicester 12.6, Nottingham 16.0, Birkenhead 18.0, Liverpool 23.6, Wigan 10.8, Bolton 14.3, Manchester 15.5, Salford 13.5, Halifax 12.0, Bradford 17.8, Leeds 18.7, Hull 11.5, Sheffield 14.7, Newcastle-on-Tyne 17.5, Cardiff 16.2, Rhondda 16.3, Merthyr Tydfil 14.8, Kings Norton 9.0, Rochdale 16.9.

METEOROLOGICAL RECORD.

For the week ending Dec. 16, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING DECEMBER 30, 1905.

R. K. McCLANAHAN, assistant surgeon. Having been examined by a retiring board and found incapacitated for active service on account of disability not the result of any incident of the service, is retired from active service on full pay from Dec. 19, 1905, under the provisions of Section 1434, Revised Statutes.

B. H. DORSEY, assistant surgeon. Ordered to Altoona, Pa., Jan. 2, for duty with recruiting party No. 4.

H. W. JUD, acting assistant surgeon. Detached from duty with naval recruiting party No. 4, ordered home and granted leave until expiration of appointment as acting assistant surgeon.

E. E. CURTIS, acting assistant surgeon. Appointed acting assistant surgeon from Dec. 21, 1905.

RECENT DEATHS.

GEORGE WASHINGTON DOANE, M.D., M.M.S.S., died in Hyannis, Dec. 28, 1905, aged eighty-one years.

JAMES LANG HARRIMAN, M.D., M.M.S.S., died in Hudson, Dec. 28, 1905.

JAMES WILLIAM HOLLAND, M.D., M.M.S.S., died in Westfield, Dec. 29, 1905. Dr. Holland was an associate medical examiner for the Western District of Hampden County. He was also a member of the Board of Health and of the local hospital staff. Dr. Holland served two years in the Philippines as an army surgeon.

DR. WILLIAM MAXWELL WHITE of Amsterdam, N. Y., who was a son of the late Dr. Joseph M. White, died from pneumonia on Dec. 29, in the fiftieth year of his age. He was graduated from Union College, Schenectady, in 1881, and from the Albany Medical College in 1885.

ANALYSIS OF ONE HUNDRED AND TWENTY CASES OF MALARIA OCCURRING AT CAMP GREGG, PHILIPPINE ISLANDS.*

BY WERTON F. CHAMBERLAIN, A.B., M.D.,
Captain and Assistant Surgeon, United States Army.

DURING the calendar year of 1901 malarial fever was by far the most common disease among the soldiers and civilians at Camp Gregg, Bayambang, Pangasinan, Luzon, P. I. A considerable number of cases, especially among the officers and civilians, have been treated at home, without being made of record. The number of admissions to hospital for paludal disease during the year, contrasted with that for 1903, is shown below:

TABLE I.

RECORD OF MALARIA IN CAMP GREGG FOR THE CALENDAR YEAR OF 1901.

| Month. | Benign Tertian. | Quar. tan. | Fatigue Autumnal. | Total | Strength Command | Per-centage |
|--------|-----------------|------------|-------------------|-------|------------------|-------------|
| Jan. | 1 | | 1 | 2 | 267 | 7.5 |
| Feb. | 3 | | 1 | 4 | 212 | 1.88 |
| March | 4 | | 2 | 6 | 225 | 2.66 |
| April | 4 | 1 | 1 | 6 | 281 | 2.13 |
| May | 1 | | | 1 | 262 | .38 |
| June | 2 | | | 2 | 266 | .75 |
| July | 5 | | 1 | 6 | 271 | 2.19 |
| Aug. | 10 | | 10 | 20 | 271 | 7.29 |
| Sept. | 18 | 2 | 3 | 23 | 277 | 8.30 |
| Oct. | 13 | | 20 | 33 | 281 | 11.62 |
| Nov. | 16 | 1 | 24 | 41 | 280 | 14.18 |
| Dec. | 6 | | 12 | 18 | 213 | 7.40 |
| Totals | 83 | 4 | 75 | 162 | 2678 | 59.53 |

TABLE II.

RECORD OF MALARIA IN CAMP GREGG FOR THE CALENDAR YEAR OF 1903.

| Month. | Cases Malaria | Mean Strength Command | Percentage |
|--------|---------------|-----------------------|------------|
| Jan. | 27 | 289 | 9.3 |
| Feb. | 21 | 315 | 6.6 |
| March | 8 | 397 | 2.6 |
| April | 12 | 294 | 4.0 |
| May | 9 | 286 | 3.4 |
| June | 11 | 335 | 3.2 |
| July | 16 | 474 | 3.3 |
| Aug. | 13 | 506 | 2.5 |
| Sept. | 14 | 319 | 4.3 |
| Oct. | 8 | 329 | 2.4 |
| Nov. | 3 | 310 | 0.96 |
| Dec. | 6 | 281 | 2.1 |

All but 3 of the 162 cases in 1901 were United States soldiers.

ETIOLOGY.

Location.—The inhabited buildings at Camp Gregg are placed on a site ranging from 60 to 80 feet above the level of the plain which extends for over 100 miles south, and at a distance of about 20 miles from the mountains on the east and west and an equal distance from the sea on the north. Elevation above the sea level not known, but is probably about three hundred feet. The distance from the post to the first houses in the town of Bayambang is about one eighth of a mile. There

are no swamps near, but in one direction rice fields approach to within one-eighth mile of the barracks and hospital. There has been a great amount of febrile disease among the natives in Bayambang.

Drainage. The natural surface drainage of the post is good, and comparatively few puddles suitable for breeding places for anopheles mosquitoes are found on the cleared portion of the reservation, even during the rainy season. The soil is for the most part loam underlaid by clay. The arrangement of the buildings is very straggling, and the reservation is large and covered with a dense and high jungle which at times has grown up to within twenty-five yards of inhabited buildings, and has rarely been kept cut to as great a distance as 100 yards from the barracks, hospital and officers' quarters. Within this jungle it was impossible to find and treat pools, and this accounts for the large numbers of mosquitoes present after the onset of the rains.

There has been no extensive upturning of the soil during the period covered by this report, and that which has occurred has for the most part been at a distance from the barracks.

Climate.—The hottest season at this station is in April, May and June, but the heat even then is not excessive for the Philippines, and the nights for the most part are comfortable, growing very cool in October and November. The rains this year began early in April, occurring almost daily by the middle of May, and showers continued to occur frequently till the end of November. The rainy season has been a light and intermittent one, just the kind which would keep pools constantly filled, yet not severe enough to thoroughly flush out all. This probably accounts for the large amount of malaria this year, as contrasted with last season, when the rainy weather began in July and was more severe and continuous during the summer and fall, thereby being less favorable to the breeding of mosquitoes.

Habitations. All barracks and quarters here are one story high, the floors being only a few feet from the ground. The doors and windows are not screened. The use of mosquito nets at night is compulsory, but many of the nets are inefficient because of insufficient length or coarseness of mesh, this being notably so in the case of the nets issued to this post by the medical department, these having a mesh of about one hundred to the square inch. Through these nets mosquitoes easily pass. As an example of how inefficient bed nets may be, either through carelessness in use or too coarse mesh it may be mentioned that during the height of the mosquito season the nets of the patients in the hospital always contained more or less mosquitoes in the morning, and on one occasion forty mosquitoes were caught in a single net, all being engorged with blood and nearly all bearing anopheles.

The sanitary condition of the inhabited buildings is good, except for the presence of the floor brush and absence of door and window screens.

Length of command. This command, one battalion of the 20th United States Infantry,

* Published by permission of the Surgeon General, United States Army.

arrived in the Philippines on Dec. 27, 1903, and at this post Dec. 31, 1903. A very few men transferred to the battalion from the troops it displaced, but the bulk of the garrison has consisted of men who had never been in the tropics, or else of those who had been in the United States for the preceding eighteen months. From time to time recruits arrived from the United States.

Water supply. — All water for drinking, cooking and bathing purposes is distilled from river water.

Race and age. — All of the cases here studied are American whites, and for the most part young men — between twenty and thirty years old.

Practice marches. — Shortly after the termination of a practice march by Company K, taking place Feb. 13 to 22, 1904, there was a marked increase in febrile diseases. No mosquito nets were used on this march. From this company there were admitted to hospital on Feb. 28, 3 cases of malaria; Feb. 29, 1 case; March 1, 2 cases of dengue and one of isolation; March 3, 3 cases of dengue; March 2, 2 cases of dengue; March 4, 1 case of dengue and 1 of malaria; March 5, 1 of dengue; March 6, 1 of dengue. Thus in thirteen days following the return of the company there were 16 admissions for febrile conditions diagnosed on the register as above. I did not see these cases, but judging from a conversation with the surgeon who attended them, and from a study of the charts, histories and treatment (all were given quinine), it appears to me probable that the cases diagnosed as dengue and insulation were in reality malarial fevers. Nearly all these men subsequently developed malarial fevers which were probably relapses from an original infection on this march.

On the succeeding three practice marches mosquito nets were used and febrile diseases did not develop as a result of the marches. Except for a ten-day practice march for each company the command this year has done garrison duty, with no hardships, overwork or notable exposure.

Mosquitoes. — In April mosquitoes at this post were very rare. An increase began in May, and the insects were very numerous during June, July and August, beginning to decrease in the latter part of September. They were present in considerable numbers in October and November and became scarce in December. During the period from May 15 to December 31 about 1,500 mosquitoes were collected and sent to the Army Medical Museum for examination. In the collection up to July 15, mosquitoes of genus *Culex* predominated (21 to 5). In all subsequent collections anopheles were in the majority. In August one shipment contained 219 of the genus *Anopheles* and 32 of *Culex*. All these collections were made either at night (8 to 10 P.M.) or about 6.30 A.M. on the inner side of screens in a screened house.

Day-flying mosquitoes have been very rarely seen during the year, and none have been collected. The usual day-flying mosquito in the

Philippine Islands is reported to be *Stegomyia fasciata* and no specimen of this insect has been found in my collections.

In the collections reported on by Miss Ludlow, of the Army Medical Museum, the following have been found: *Culex microannulatus*, Theob. C. gelidus, Theob.; *Culex annulifera*, Ludlow; *Culex concolor*, Desv.; *Culex fatigans*; *Mimomyia chamberlaini*, n. sp. Ludlow; *Mansoni annulifera*, Theob.; *Myzomyia (anopheles) ludlowi*, Theob.; *Myzomyia (anopheles) thomtonii*, Ludlow; *Myzomyia (anopheles) rossii*, Giles, var. *indefinata*, n. v. Ludlow; *Nyzzorhynchus (anopheles) thilip*, Ludlow; *N. (anopheles) fuliginosus*, Giles; *Myzorrhynchus (anopheles) barbirostris*, Van der Wulf; and *Stegomyia scutellaris*, Walker.

INCUBATION.

The only facts bearing on this point are those relating to the practice march above mentioned. It appears probable that the febrile cases admitted were infected during the march, which was of ten days' duration. Of these cases 12 came in within ten days after the return of the company. This is consistent with the incubation period of nine to ten days mentioned by Craig, but as the presence of the plasmodia was demonstrated only in four cases the remainder of the diagnoses are not certain, neither can infection prior to departure or subsequent to return be excluded.

IMMUNITY.

Nothing has been observed pointing to immunity of any. The percentage of cases among the commissioned officers and their families has been less than among the enlisted men, but this is believed to be due to greater care in the use of mosquito nets, to the fact that they do not spend their evenings in town among the natives and also to some extent to the use of quinine as a prophylactic.

Of the 120 analyzed cases of malaria 24 are recurrences in the same individual. Of these 24 cases at least 4 were proved to be new infections by finding a type of plasmodia different from that demonstrated on the first entry. All these new infections and also six of the recurrences (probable relapses) occurred while the patients were on a compulsory course of treatment consisting of .5 gm. quinine sulphate in solution three times a week. This treatment had been in effect several weeks in each case when fever occurred. On Dec. 11, the compulsory course was increased to .5 gm. four times a week, and since then there has been one relapse and one new infection among the men taking this treatment. These cases prove that neither 1.5 gm. nor 2 gm. quinine sulphate in solution a week is sufficient in all cases to prevent relapse or new infection.

CLASSIFICATION.

The number of cases and the classes of malarial fever occurring during the period from Jan. 1 to Dec. 31, 1904, are shown in Table I, tabulated according to months.

There came under my personal observation

and care, subsequent to April 13, 1904, 120 cases which were sufficiently complete in history, chart and blood findings to make them of value for analysis and on these the following remarks are based. Three hourly charts were kept in all these cases from 6 A.M. to 9 P.M. These 120 cases are classified as follows: Quartan intermittents, 3; benign tertians, 55, of which 28 were single infection intermittents, 23 were double infection intermittents (quotidian) and four were remittent or continued; malignant infections (estivo-autumnal), 62 cases, of which 24 were tertian intermittents, 16 were quotidian intermittents and 22 were remittents. In these 120 cases plasmodia were found in 113, the failure to find the plasmodia in 7 being due to a lack of cover glasses during a portion of August. All those in which plasmodia were not found were typical benign tertian fevers.

There was in the series one pernicious case, and no other presenting any alarming symptoms further than rises in temperature to 106.5° F. No cases of malarial cachexia developed. The case of pernicious fever developed in a civilian engineer living and working at the distilling plant one-half mile from the post. He had neglected treatment for first attack.

QUARTAN INTERMITTENTS.

Only three of these infections were observed, two being in September and one in November. Typical parasites were found in all. Severe chill was noted in one, slight chill in one and no chill in the third. All cases complained of headache and pain in back and limbs, and one was nauseated at time of paroxysm. The temperature during paroxysm reached between 104° and 105° F. in one case and was below 104° F. in the other two. No paroxysm occurred after beginning quinine treatment.

BENIGN TERTIAN INFECTION.

Of the benign tertian cases the double infections increased markedly as the season advanced. The plasmodia were demonstrated in 18 of the 55 cases diagnosed as benign tertian fever, and in many of the cases of double infection the two crops of parasites were easily demonstrated in the blood. In several cases nearly all stages of the parasite could be found on the slide, yet the fever was a typical intermittent tertian and not quotidian or remittent as had been predicted from the blood examination. The appearance of the organisms agreed entirely with the usual description in the textbooks.

In one of the benign tertian cases a round flagellated plasmodium was seen, the pigment in the main body of the organism being very sluggishly motile and the flagellum having a rounded pigmented knob at its proximal end in contact with the periphery of the main body and no clubbing at its distal extremity. The flagellum was very active. In about ninety seconds the knob of the flagellum fused with the main body of the parasite, the pigment in the organism

became exceedingly active and the flagellum faded away. It is thought that this was a so-called passive flagellated form (Craig), the main body being a macrogamete and the flagellum being an escaped one (microgamete) which fused with and fertilized the macrogamete. From the literature available here it appears that this process has very rarely been observed in the blood specimen.

The three-hour temperature charts in four of the benign tertian infections showed a remittent temperature extending over a period of several days. Three of these occurred in September and a fourth in November. Typical tertian plasmodia were found in all. Three of the cases were characterized by slight chills and the fourth by merely chilliness. The highest temperature rise was between 104° and 105° F. in 3 cases.

Of the benign tertian intermittents (single infections) one occurred in April, one in May, one in June, two in July, seven in August, six in September, three in October, five in November and two in December. Of the double benign tertian infections (quotidian intermittents) two occurred in July, one in August, four in September, five in October and nine in November and two in December.

Taken together the benign tertian infections exhibited the following points of clinical interest: Severe chills at the time of the paroxysm were noted in 28 patients, slight chills in 12, merely chilliness in 5 and no chill or chilliness in 10. Nausea has been a frequent and distressing symptom in all varieties of malarial fever in this series, and in the 55 benign tertian cases it occurred in 29 and vomiting in 17. This gastric disturbance was usually present only during the period of the paroxysm. Diarrhea was noted in one case. Abdominal pain of greater or less degree was complained of in 7 cases. It was usually accompanied by tenderness, and in one case simulated appendicitis. Cough was present in 9 cases and pain in the chest in 1. Headache was a prominent symptom during the febrile period in 34, and bone, muscle or joint pain, more or less generalized, in 24 cases. Herpes was noted on the lips in 4 cases.

The temperature at its highest point (as recorded every three hours) was between 104° and 105° F. in 19, between 105° and 106° in 2 and between 106° and 107° in 2. A pseudocrisis and precrisis rise in one or more of the paroxysms was observed in 5 cases, of which 4 were double infections (quotidian) and one single. This resembled the pseudocrisis and precrisis rise described by Craig and others in malignant tertian intermittents, except that in not all of the cases was the precrisis rise higher than the maximum before the pseudocrisis. No marked drops below normal following paroxysms are shown on the charts. In all of the cases shown, the pseudocrisis the diagnosis was confirmed by finding unmistakable benign tertian plasmodia.

In 16 cases one paroxysm occurred after beginning quinine treatment 1.5 gm. 4 times a day in solution) and in 4 cases 2 occurred. In 2 cases

paroxysms and all fever ceased spontaneously, or as a result of rest in bed and cathartics, before quinine was administered.

MALIGNANT (ESTIVO-AUTUMNAL) INFECTIONS.

The prevalence of the estivo-autumnal infections by months is shown in table in Charts 1 and 2.

Parasites.—In the 62 cases of the estivo-autumnal infections here studied the plasmodia were found in all. While clinically the estivo-autumnal intermittent fevers could be clearly divided by the three-hourly chart into tertian intermittents and quotidian intermittents (as described by Manson, Craig and others), we could not detect the constant differences described by these writers as characteristic of the plasmodia in these two clinical types, and we are inclined to agree with Thayer that the differences between the two varieties of organism described are so slight that they are probably due to variations in the length of the cycle of development. The large pigmented form, one-half size of corpuscle (which seems to be the most characteristic and easily recognized distinctive feature as given by Craig), was seen in only 1 case in this series. With this one exception the largest pigmented forms seen filled from $\frac{1}{2}$ to $\frac{3}{4}$ of the corpuscle, and these were found in 7 out of 24 tertian intermittents, and in 1 out of 16 quotidians. Pigmented forms $\frac{1}{2}$ the size of the corpuscle, or smaller, were found in 6 of the tertians and 1 of the quotidians. No differences in the ameboid bodies and ring forms could be detected in the two clinical types.

In making these remarks it is recognized that the significance of such a small series of cases is not great, and also that the examinations of the bloods in many cases were not frequently repeated because of the necessity of curing the patients and returning them to duty within a reasonable time.

Crescents were found only twice, due to the fact that the patients were received promptly on appearance of first symptoms and were treated with quinine before the usual time necessary for development of crescents had elapsed.

No important changes in the size, shape or color of plasmodium containing blood corpuscles in the estivo-autumnal cases were observed. In the benign tertian cases the infected blood corpuscles were always enlarged and pale when pigmented forms were found.

Malignant (estivo-autumnal) tertian fevers.—There were 24 cases so classified on clinical grounds. The three-hour temperature chart showed a pseudocrisis and precritical rise of temperature in one or more paroxysms in 11 out of the 24 cases. In most of the malignant tertian infections the febrile stage was of long duration, frequently eighteen hours and sometimes twenty-four. In a few, however, there was a sharp rise and an equally rapid fall, the febrile reaction lasting about nine hours without pseudo-crisis, and the chart resembling that of a benign tertian fever. In six cases the maximum rise was between 104° and 105° F.; in 9 cases between 105°

and 106° , and in 3 between 106° and 107° . In 10 cases one paroxysm and in 3 cases 2 paroxysms were observed after beginning treatment with quinine. Severe chills occurred in 9 cases, slight chills in 4, chilliness in 2 and no chill or chilliness in 9.

Malignant (estivo-autumnal) quotidian fevers.—There were 16 cases of this type. The three-hour curve showed a pseudocrisis and precritical rise in 3 cases. In 7 cases the maximum rise was between 104° and 105° F., in 1 from 105° to 106° and in 2 above 106° . Severe chills were noted in 6, slight chills in 6, chilliness in 1 and no chill or chilliness in 3. Three had 1 and four 2 paroxysms after beginning quinine.

Malignant (estivo-autumnal) remittent or continued fevers.—Twenty-two of these were observed, 2 having tertian paroxysms, 13 quotidian and 7 showing no characteristic periodicity in febrile reaction. These cases varied from marked remittents to continued fevers with very slight daily remissions. None continued over a week. Estivo-autumnal plasmodia were demonstrated in all.

The temperature curve reached a point between 104° and 105° F. in 10, between 105° and 106° in 4 and above 106° in 3. Severe chills occurred in 6 cases, slight chills in 6, chilliness in 5 and no chill or chilliness in 5. After beginning quinine, fever continued for one day in 5 cases, for two days in 3 and for three days in 6.

Considered together the estivo-autumnal infections showed the following points of clinical interest:

Nausea and vomiting was marked and annoying symptom. Out of the 62 cases nausea occurred in 38, and vomiting in 23. These symptoms in most cases were confined to the period of marked febrile reaction. Diarrhea was noted in 7 cases. Abdominal pain, in most cases associated with tenderness on palpation, was recorded in 18 cases. Forty-seven patients complained of headache, and 41 of more or less generalized pain in back and limbs. Cough was present in 11 cases, and herpes on the lips in 3. Urticaria occurring at the time of paroxysms and ephemeral was noted in 2 cases.

No case with infection by two types of plasmodia was detected and no cases resisting quinine and resembling typhoid were observed. During the period between Jan. 1 and Dec. 31, there were 11 diagnoses of dengue and 7 of fever of undetermined causation. All but 1 of the cases diagnosed as dengue occurred in March after the practice march referred to above. One case of pernicious malaria of gastralgie and cardialgie type was observed and a history is appended.

In all cases of malaria the urine was examined. Albuminuria was not noted in any case.

PROPHYLAXIS.

All practicable means were employed to grade and clear the site of the military post, and pools on the cleared part of the reservation were oiled three or four times a month. No larvæ were at any time found growing in pools on the post,

though often looked for. The use of mosquito nets at night was compulsory. Each case of malaria after being discharged from the hospital received a compulsory course of quinine, lasting for a period of ten weeks. This was administered regularly at the hospital under supervision of a sergeant, so could not be neglected. That 2 gm. quinine sulphate, in solution, weekly, is not in all cases prophylactic against infection or relapse is shown above.

TREATMENT.

Rest in bed, liquid diet and in most cases a cathartic, usually calomel followed by magnesium sulphate, was a routine treatment. When quinine was administered it was given in doses of .5 gm. in solution 4 times daily during the stay in hospital, unless this was unduly prolonged by some pathological condition other than the malaria. On leaving the hospital each patient was required to take the following course of quinine sulphate treatment: For two weeks .5 gm. twice daily, at the end of which .5 gm. three times weekly was given for two months. At the end of two months .5 gm. daily was given for a week.

Quinine was given in solution, except when it caused nausea and vomiting, in which case capsules or tablets were substituted. The action of quinine has been found efficient and prompt in all cases. Arsenic was given in addition to quinine in a few of the recurrent cases.

In this series of malarial cases the blood examinations were made by Lieut. S. J. Morris, Assistant Surgeon, and by myself, and in nearly all cases each form of the parasite was examined by both.

CASE IX. Pernicious estivo-autumnal malarial fever.—Late in the afternoon of Nov. 26, 1904, a case of pernicious malarial fever was admitted, the history of which is as follows:

Engineer, running distilling plant located at edge of river in Bayambang, P. I., one-half mile from Camp Gregg. Age twenty-nine. Born in California. Family history unimportant. Lives in house adjacent to distilling plant. Uses alcohol to excess.

Previous history.—Has been in Philippine Islands continuously six years and at Bayambang for twenty-eight months. Has never slept under a mosquito net. Had malaria in United States eight years ago. Smallpox two years ago. Oct. 15, 1904, had chills and fever and took quinine for two or three days. Chills and fever recurred about Oct. 25 and took quinine in tablet form at irregular intervals up to Nov. 20.

Present illness.—Nov. 24, slight chill in forenoon and fever in afternoon with headache and general pains. No nausea. Bowels regular.

Nov. 25, slight chill about 10 a.m. and slight fever in afternoon. Vomited dinner about 1 p.m. Headache. No general pain. No diarrhea. Took 1.2 gm. quinine to-day in tablet form.

Nov. 26, felt fairly well in forenoon and worked till 2 p.m. Bowels moved once in morning. About 11 a.m. fever, general pain and headache came on. Vomited dinner at 12.30 and emesis continued all the afternoon. At about 4 p.m. blood appeared in the ejected material. About 3 p.m. abdominal pain began to come on and quickly became excruciating. At the same time diarrhea began. About 6 watery stools in first half

hour after which stools continued frequent but less often. A hard chill came on about the time of the abdominal pain.

At 4 p.m. patient was seen by Lieutenant Morris, Assistant Surgeon. The chill was just passing off. Vomiting was continuous, the vomitus being first yellow and then blood stained. Had two large watery stools within a few minutes consisting of bile stained fluid containing flakes of mucus. Not "rice watery" in appearance. Skin felt hot. Pulse 100, strong and full. Advised to enter hospital at once.

After this patient worked for one-half hour about the distilling plant and came to hospital in a carriage, arriving about 5 p.m.

When first seen by the writer, about 5.25 p.m., patient was in a state of extreme collapse. Examination showed a well-developed and poorly-nourished man. Face drawn and pinched, bearing the stamp of impending death. A marked cadaveric odor. Eyes sunken, eyeballs very brilliant and in constant motion. Patient very restless, groaning and crying out, complaining of severe epigastric pain and throwing himself about in the bed. Also complained of pain over apex of heart. Moderate perspiration. Trunk warm (not hot), legs cool, hands and arms extremely cold and clammy. Respiration shallow and hurried. Tongue dry and glazed. Abdomen slightly retracted, almost entirely flat on percussion and an area just below tip of sternum about the size of a dollar which was extremely tender. No other tenderness.

Pulse scarcely perceptible at wrist and could not be counted. Heart's action feeble but regular and 158 beats to the minute. Nothing abnormal heard in lungs. Temperature by mouth at 5.10 p.m. and 6.30 p.m., 98.6. Temperature by rectum at 6.30 p.m., 106.8.

There was no hicough. Voice was husky. Intense thirst was complained of and when seen much ice water was being drunk and soon rejected. Vomitus slightly pink. Slight muscular cramps in the left calf muscles were complained of. There were two watery evacuations in the first half hour in hospital.

Progress of case.—Patient was given by hypodermic injection .016 gm. morphine sulphate and .002 gm. strychnine sulphate at 5.40 p.m. Hot water bag and warm bedding. At 6 p.m. .4 gm. quinine sulphate in capsule given by mouth and retained an hour. At 6.25 .002 gm. strychnine sulphate given hypodermically. At 7 p.m. .5 gm. quinine sulphate dissolved with .25 gm. tartaric acid and boiled was injected into the left buttock. The pulse at this time was slightly improved, irregular in force of beat and uncountable. Heart beat as before and 152 to minute. Pain relieved by morphine and vomiting and diarrhea checked.

Strychnine .001 gm. and brandy 4 cc. hypodermically every two hours, beginning at 8 p.m., was ordered and continued through the night.

At 9 p.m. extremities were warmer, pulse somewhat improved. Heart beat 132 per minute. Temperature by rectum 102.1 F. Given calomel .2 gm.

At 11 p.m. patient comfortable. Pulse could be counted and had fallen to 116. An intermuscular injection of .5 gm. quinine sulphate was given in the right buttock.

At 12 p.m. patient was quiet but had slept none. Pulse 108. Temperature (by mouth) 100°. Given .008 gm. morphine sulphate hypodermically to induce sleep.

Nov. 27, 9 a.m. Patient in good condition. No vomiting or diarrhea since 9 p.m. Pulse of fairly good strength and volume, 90 per minute. Temperature 97.8°. Ordered quinine sulphate in .5 gm. doses four times a day and with each dose .001 gm. strychnine and 8 cc. brandy, all by mouth. Also in addition to

the above .5 gm. quinine sulphate by intramuscular injection at 1 P.M. This treatment produced no symptoms of cinchonism. Magnesium sulphate 30 gm. had been given at 7 A.M., and this produced two evacuations. Urine negative.

Nov. 28, 9 A.M. Patient in excellent condition. Temperature 99.4°. Pulse of 86 and of good strength.

Blood.—An examination by lamp light failed to reveal any organisms the night of entry. Nov. 27, in the morning, many actively aneoboid hyaline estivo-autumnal plasmodia from $\frac{1}{8}$ to $\frac{1}{4}$ filling normal sized

corpuscle were seen. Nov. 28, a pigmented body, at first with active pigment in a wreath form was seen. In ten minutes the pigment lost its motility but retained its ring arrangement, and the body appeared vacuolated and disintegrating. This was probably the "passive flagellated form" (macrogamete), described by Craig, prior to arrival of any flagella.

Diagnosis.—This case is considered to belong to the gastric and cardiac type (as described by Craig and Thayer) with several of the symptoms of the cholerae form added. Because of the impossibility

CASE I.

Diagnosis: Malarial fever, intermittent, quotidian (double benign tertian). Patient entered hospital for alveolar inflammation about a carious tooth. Malaria developed on second day in hospital. No plasmodia were found till Nov. 26, though repeatedly searched for several times daily by two physicians. On Nov. 26 two crops of benign tertian parasites were found, the number of parasites being small. The alveolar inflammation did not progress to suppuration.

CASE III.

CASE II.

Diagnosis: Malarial fever, remittent, acute, due to benign tertian parasites. There was a moderate chill Sept. 13, 7 P.M., and none afterwards. The temperature dropped to normal on the third day and before any quinine was administered. Typical benign tertian plasmodia were demonstrated in the blood.

Diagnosis: Malarial fever, intermittent, quotidian (double benign tertian). The blood examination showed two crops of typical benign tertian plasmodia. The first paroxysm shows a pseudocrisis and authors as characteristic of the malignant tertian infections. Several other benign cases at Camp Gregg showed this pseudocrisis.

CASE IV.

Diagnosis: Malarial fever, continued type, due to estivo-autumnal (malignant) infection. Estivo-autumnal plasmodia were demonstrated in large numbers in the blood. Quinine was begun Nov. 7 in doses of 8 gm. four times a day in solution. The temperature did not reach normal till Nov. 12. This case was the most resistant to quinine of any of the cases observed at Camp Gregg.

CASE VI.

Diagnosis: Malarial fever, intermittent, malignant quotidian (estivo-autumnal). Estivo-autumnal plasmodia demonstrated in the blood. This patient had a severe chill 9 a.m., Nov. 20, and another 8 a.m., Nov. 22. No chills occurred after Nov. 22, but there was marked nausea, vomiting and abdominal pain at time of febrile paroxysms. The chart does not show a pseudo-remission when charted every three hours. The third paroxysm was charted hourly and then showed a marked pseudo-remission (18°) between 11 a.m. and 1 p.m.

CASE V.

Diagnosis: Malarial fever, intermittent, malignant quotidian (estivo-autumnal). The estivo-autumnal plasmodia were demonstrated in the blood. Each one of the paroxysms shows a distinct pseudo-remission and prefebrile rise of temperature. In each paroxysm the pseudo-remission began at the same hour, noon.

CASE VII.

Diagnosis: Malarial fever, intermittent, malignant tertian (estivo-autumnal). Estivo-autumnal plasmodia demonstrated in the blood. The second paroxysm shows the characteristic pseudo-remission in the blood by M'Connell, Craig and others and shows the long incubation time, febrile period before 6 a.m. till past 3 p.m., which is not seen in the shorter paroxysm seen in the benign tertian fevers.

of at once absolutely ruling out Asiatic cholera, which had been very prevalent here the preceding year, such precautions as would be of use in preventing the spread of cholera were at once put in practice.

From the condition of the patient at the time of entry it is believed that death would have been inevitable in a few hours if vigorous treatment had not been instituted.

DEDUCTIONS.

From the facts presented in this report the important deductions drawn are as follows:

1. That the great prevalence of malaria in 1904 was probably due to the presence of a remarkably large number of mosquitoes of the genus anopheles. The possibility of drinking water infection can almost certainly be excluded.

2. That the abundance of mosquitoes in the post resulted from the close approach of the jungle rendering the location and treatment of breeding pools impossible.

three times or even four times a week, will not in all cases prevent infection or relapse, though it usually does.

9. That malarial infections both benign and malignant existing for several days without chills or chilliness but with marked periodical febrile paroxysms were by no means infrequent.

10. That clinically the estivo-autumnal infections could be clearly divided into remittent, quotidian intermittent and tertian intermittent. Of 62 cases 40% were tertians, 25% quotidians and 35% remittents.

11. That in 46% of the estivo-autumnal tertian intermittents a pseudoerisis and precritical rise of temperature was present in one or more paroxysms as shown by three hours chart.

12. That an almost identical pseudoerisis and precritical rise was observed in 9% of the benign tertian intermittents.

13. That no distinctive differences were ob-

CASE VIII.

Diagnosis: Malarial fever, intermittent, malignant tertian (estivo-autumnal). Estivo-autumnal plasmodia demonstrated in the blood. The third paroxysm shows a moderate pseudoerisis and also the long duration of the febrile period.

3. That the dangerous character of these pools was augmented by the long-continued wet season and intermittent occurrence of the showers and absence of many heavy rain storms.

4. That the prevalence of malaria increased as the season advanced, from May until December, in which month the disease began to decrease.

5. That the severity of malaria increased in the fall, especially in October and November, as shown by a rise in the number of estivo-autumnal and double tertian infections.

6. That quartan infections were infrequent in this vicinity.

7. That pernicious malaria did not occur at this post, probably because of thorough and prolonged treatment of the primary infection. The pernicious case reported in this series developed in the adjacent town.

8. That quinine sulphate in solution, .5 gm.

served in the parasites in the intermittent tertian and intermittent quotidian estivo-autumnal infections.

14. That nausea, vomiting and abdominal pain at time of paroxysm were extremely common in both benign and malignant infections. In 120 cases analyzed nausea occurred in 72%, vomiting in 42% and abdominal pain in 30%.

A REPORT OF THREE CASES OF PERFORATED GASTRIC ULCER; GASTRO-ENTEROSTOMY.

BY DANIEL FISKE JONES, M.D., BOSTON.

Surgeon to Out-Patients, Massachusetts General Hospital.

GASTRO-ENTEROSTOMY in cases of perforated gastric ulcer may be discussed from an entirely different point of view than when considered in relation to simple uncomplicated ulcer. In the

latter case one must be convinced that the operation is going to be of permanent value to the patient or at least it must be of greater value than medical treatment, and the proof of this has not been thoroughly convincing up to the present time. In cases of perforated ulcer the patient must be operated upon, there is no choice between medical and surgical treatment; here the immediate condition of the patient is the important consideration so that one does not have to look ahead one or more years to see whether the operation is going to be of value then, so long as nothing is done to make the condition of the patient worse. The condition is such a serious one that we must consider every means to get the patient out of his present predicament. Gastro-enterostomy, then, may be considered as an operation for temporary relief and not necessarily as a permanent cure for the ulcer, though of course such a result may be attained.

Let me state at once that I am well aware that gastro-enterostomy cannot be done in every case of perforated gastric ulcer, nor do I believe that it is necessary. The number of patients, however, who will stand the extra shock of the operation is, I believe, much larger than is generally supposed. The great advantage, after operation, of the anastomosis will more than compensate for the slightly increased shock in most cases.

Although the operation is of particular value in cases where the perforation is situated at or near the pylorus or in the duodenum, it is a useful procedure in ulcer in any portion of the stomach.

Some of the reasons why gastro-enterostomy is of particular value in perforated ulcers are the following:

The ulcer is in an active state and presumably will continue to be active for some time regardless of treatment. Rest in bed, resting of the stomach, and feeding by rectal enemata cannot arrest the activity of the ulcer at once, and so long as the ulcerations remain active there is danger from hemorrhage, perforation of other ulcers, and involvement of the sutures closing the ulcer causing leakage. In spite of the experimental findings of Cannon and Blake that the greater portion of food is forced through the pylorus after a gastro-enterostomy, there must be some change produced by the operation which relieves the irritation of the ulcer, for it does give the greatest relief at once, and so far as we have any means of telling, the ulcer has a much better chance to heal.

In 20% of the cases of gastric ulcer the ulcerations are multiple (Mayo), and so long as these remain active there is a possibility, though perhaps a slight one, of a second perforation. A case operated upon by Dr. M. H. Richardson for perforated ulcer was apparently getting well when a second perforation occurred causing the death of the patient. Every effort should be made to prevent such an occurrence.

Pain is often a most trying symptom of gastric ulcer and this, added to the pain and discomfort of an operation, is very wearing on the patient. In all three reported cases the relief from pain after

operation was immediate, and permanent in cases II and III. That the pain of gastric ulcer is severe may be judged by the relief which the patients two and three expressed the first day after the operation. Both patients though they complained of some pain in the wound said that they had less pain and discomfort than they had had for some time previous to the operation.

In the three cases presented, the difficulty of closing the perforation in a satisfactory manner without narrowing the pylorus was the chief reason for the gastro-enterostomy. The large area of hard inflammatory tissue about the perforations made it impossible to close them satisfactorily in any case. In Case I an area of normal stomach to the left was folded over the perforation and simply caught there by a few sutures. In cases II and III after a very unsatisfactory suture some of the gastro-hepatic omentum was brought down over the opening. To have excised the ulcer with sufficient of the inflammatory area to have permitted a satisfactory suture would have made pylorotomy necessary, and gastro-enterostomy was considered much the less severe of the two. Gastro-enterostomy gave the ulcer a chance to heal and prevented any strain upon the weak line of sutures by giving free drainage at the lowest point, thus avoiding to a considerable extent the possibility of further leakage.

There may be a partial obstruction at the pylorus due to recent inflammatory changes, to cicatricial contraction of an old ulcer, or to some other cause not evident in a hurried examination, in all of which conditions a gastro-enterostomy would be a great benefit, at least, temporarily.

The problem of feeding these patients is a serious one, for many of them are in a wretched condition from hemorrhage, lack of nourishment and suffering, besides many of them have to withstand a long siege of sepsis, which makes a long period of rectal feeding impossible. Gastro-enterostomy is for these reasons of the greatest advantage, for the patients can begin liquids by mouth at once.

Besides these advantages we have the possibility of curing the patient permanently.

That there are disadvantages in this operation cannot be denied. We are putting an extra load on a patient already in poor condition and in considerable shock. It does take a few minutes longer but the shock of a gastro-enterostomy seems to be extraordinarily slight. In cases I and III the patients were in wretched condition, yet the gastro-enterostomy, which came after suture of the perforation and flushing of the abdomen, seemed to affect their condition very little.

Another objection to this operation in these cases is the danger of "circular vomiting" which must be expected in a certain small proportion of cases. None of the more elaborate methods which have been devised to avoid this catastrophe can be used because they require more time than the simpler methods. With a posterior gastro-enterostomy and a short loop of jejunum the ob-

currence of this condition is so rare that it need hardly be considered seriously.

Peptic ulcer of the jejunum is a remote danger of the operation but this also is so rare that it need not be considered as a reason for not operating in these cases.

The advantages of the operation when the patient is in a condition to stand the extra time required for it far outweigh the disadvantages, and gastro-enterostomy, if ever justified, certainly is in these cases whenever the condition of the patient will permit.

Posterior gastro-enterostomy by simple suture either with or without clamps with a short loop, or better no loop, of jejunum (Moynihan's operation) is to be preferred where it is possible to use it. Where clamps are used the greatest care should be taken to avoid injury to the mucous membrane for fear it may be the starting point of other ulcers.

The Murphy button, I believe, should not be used in these cases. This is also the view of F. König (*Zeitschrift für ärztl. Fortbildung*, 1904, IV, 1).

The McGraw ligature, though somewhat more rapid than simple suture, is not applicable to these cases. It seems to me, because one must wait from three days to a week before drainage is established, while it is of the greatest value to have an immediate opening.

CASE I. K. M., female, aged thirty-two, married, was seen in consultation with Dr. N. C. King of Brockton, Nov. 24, 1902.

The patient had had symptoms of gastric ulcer for about ten years, and had been on rectal feeding at intervals during all that time. Her stomach, she said, "was never right." Two days before entrance she had had an attack of severe pain in the left hypochondrium which gradually quieted down so that she could do her work. The morning before entrance she had another severe attack of pain in the left side of the abdomen, and at 3 P.M. she had still another, much more severe than the other two, so severe in fact that she fell to the floor and would allow no one to touch her.

Dr. King saw her at 6 P.M., when he found her in a profound shock, temperature 97.6°, pulse 76 and very feeble. There was marked rigidity of the abdominal muscles with intense general abdominal pain and pain radiating into the left shoulder. I saw her at the Brockton Hospital at 11 P.M., eight hours after the last attack of pain.

Operation. — An incision was made through the left rectus over the point of greatest tenderness and where an indefinite mass could be felt. The greater curvature of the stomach presented in the wound, adherent to the abdominal wall. The whole abdomen above the greater curvature in the middle and above the colon on either side was filled with stomach contents, and the pelvis with cloudy fluid. On the anterior wall of the stomach near the middle and about three inches from the pylorus was a perforation the size of a lead pencil. This was situated in about the center of a very much thickened and hardened area 3½ inches in diameter, extending upward over the lesser curvature and downward to the greater curvature. To close the perforation by sutures was impossible and to excise it meant a resection of a large part of the stomach, which the patient was in no condition to stand. A fold of normal stomach to the left was brought down over the opening and caught there roughly by a few catgut sutures.

An anterior gastro-enterostomy was then made with a Murphy button. Four gauze wicks were put in, one to the foramen of Winslow, one to the line of sutures and one into either flank.

The patient stood the operation remarkably well considering her condition before. Rectal feeding was begun at once, water in small quantities was begun in twelve hours and broth in twenty-four hours, and the quantity of both gradually increased.

The stomach folded over the original perforation unexpectedly prevented any leaking from it, but nine days after the operation there appeared a small perforation an inch below the original, in that portion of the stomach presenting in the wound. This gradually enlarged in spite of rectal feeding and absolute rest for the stomach. The patient was therefore put on to feeding by mouth again as she was going down hill rapidly; this apparently changed the conditions somewhat, for the ulcer began to close. Unfortunately, a third ulcer appeared at this time just below the second. It was impossible to nourish the patient sufficiently now, and she died of exhaustion, three weeks after the operation.

After death the Murphy button was found in the stomach in the region of the ulcers.

CASE II. W. R., male, aged forty-eight, was seen in consultation with Dr. J. P. Shaw of Brockton, Nov. 11, 1904.

For eight years the patient had had symptoms of gastric ulcer. For four years he had had hemorrhages from the ulcer two or three times a year. The last hemorrhage occurred three months previous to the perforation and was so severe that the patient became very much exsanguinated. During the last few years he had been on rectal feeding at frequent intervals.

For two weeks prior to operation the patient had had a good deal of distress about one hour after eating. Four days before operation he began rectal feeding, but on the next day he had soft stool and an egg for breakfast, and then went down town to vote.

The next day he had soft food all day, and vomited once. The following day he went on to rectal feeding again. At noon time, after eating some soft food, he had a little pain in the epigastrium. At 7 P.M., while sitting reading, he had a terrific abdominal pain, and immediately went to bed. He was given morphia gr. ¼ with no relief. An hour later the temperature was 97.2°, pulse 120.

At 9 A.M., the next morning, when I saw him, the patient was somewhat easier, but his abdomen was rigid and tender, his respirations short and jerky and his expression anxious. Temperature 100°, pulse 108. He was removed to the Brockton Hospital and the operation begun at 12.10 P.M. An incision was made through the right rectus; upon opening the abdomen, the transverse colon presented; below this the abdomen was nearly normal in appearance, while above, the omentum was adherent to the abdominal wall. The lower part of the abdomen was walled off with gauze, after which the adhesions were broken down, allowing a large quantity of fluid and stomach contents to escape from above the stomach. A perforation was seen exactly on the lesser curvature, an inch from the pylorus, surrounded by a hardened area 2½ inches in diameter. It would have been impossible to have excised this area without doing a pylorotomy, which was not to be considered under the circumstances. The perforation was therefore closed as well as possible and some of the gastro-hepatic omentum brought down over it. A posterior gastro-enterostomy was then done with a short loop and simple suture, after which the whole infected area, including the lesser peritoneal

cavity, was washed out. Wicks were then placed into the lesser peritoneal cavity and to the site of the perforation.

The convalescence was uninterrupted in this case, with immediate relief of symptoms. He was given water in small quantities the first twenty-four hours, after which broths in small quantities were added and gradually increased.

The relief which this patient experienced immediately was most marked; every time I saw him he expressed his surprise at the slight discomfort from the wound and the great relief the operation had given him.

CASE III. T. R., male, aged twenty-five, married, tailor.

This patient was first seen by me on Nov. 14, 1904, at his place of business.

He had had symptoms of hyperacidity for somewhat over a year.

Three days before, Nov. 11, he had had an attack of pain in the right iliac region with vomiting. The pain subsided after twenty-four hours but soreness remained for twenty-four hours longer. At 3 p.m., on the day I saw him, two hours after a light lunch of a sandwich and coffee, the patient again had an attack of pain in the right iliac fossa similar to the one three days before; there was, however, no vomiting. When I saw him at 4 p.m., he was lying with his knees drawn up, with marked tenderness and some rigidity over the right iliac fossa; over the rest of the abdomen there was no tenderness or rigidity; there was pain, however, referred to the region of the appendix whenever pressure was made on any part of the abdomen. There was also a reddened area over the appendix where the hot water bottle had been.

The patient was sent to St. Margaret's Hospital at once for appendectomy, as the diagnosis was appendicitis in spite of the earlier gastric symptoms which the patient made very light of at that time. Another point which suggested appendicitis was the attack of pain in the right side three days before, with tenderness remaining in that region for two days.

While waiting for his parents to get to the hospital the patient had a most terrific attack of general abdominal pain; he was pale and perspiring, his pulse was small and feeble and vomiting was constant.

When I arrived an hour later it was evident that the condition had changed from a local to a general one, and without stopping to examine the patient it was taken for granted that the appendix had perforated, causing a general abdominal infection.

Operation.—An incision was first made over the appendix when the abdomen was seen at once to be full of stomach contents and the appendix to be normal in appearance. This incision was left open and another made through the right rectus downward from the costal border close to the median line. A perforation the size of a lead pencil was seen on the lesser curvature about an inch from the pylorus. This opening was surrounded by a very much thickened and hardened area extending from the pylorus, upward, somewhat on to the posterior wall and downward toward the greater curvature.

The only possible way to excise the area was to resect that portion of the stomach with the pylorus, which was, of course, impossible with the condition of the patient. To make a suture that would hold seemed impossible. A single row of Lembert sutures of catgut was put in, drawing the walls together as well as possible and some of the gastro-hepatic omentum caught over this.

A posterior gastro-enterostomy was then done by the simple suture method.

The whole abdomen including the lesser cavity was

washed with salt solution, a wick put into the lesser cavity, one into the pelvis and one to the line of sutures over the perforation.

The after treatment was the same as in cases I and II. The marked relief which this operation gave was very noticeable, for the morning following the operation the patient expressed himself as having had a very comfortable night, and from that day until he left the hospital his only complaint was that he did not get enough to eat.

The only complication in this case was a very mild stitch hole infection with no temperature, about twelve days after the operation. Just before the stitches were removed the patient said that the wounds felt rather sore, but they were both very dry and the stitches had not cut. Three days after removal of the stitches hardened areas could be felt about some of the stitch holes but very deep. These areas finally became more superficial and were opened, when a very thick tenacious pus escaped from the sub-peritoneal space. The surface of the wound was so dry and clean, and the infection started so deep and was so long getting to the surface that it seemed to me to be a case of infection of the stitches from the peritoneal surface rather than from the skin.

The points of interest in the above cases are as follows:

All cases were perforations of chronic ulcers, the history of ulcer varying from one and one-half to ten years. The perforation occurred in the midst of a large indurated and thickened area which made it impossible to close the perforation by sutures with any degree of security.

The ulcers were located, in cases II and III, about an inch from the pylorus, directly on the lesser curvature, while in Case I it was about 3 inches from the pylorus and 14 inches below the lesser curvature. The situation of the ulcers and the extent of the stomach wall involved by the chronic inflammatory process made resection of the ulcer and indurated area impossible without resection of the pylorus, while closure of the ulcer by suture without resection was very unsatisfactory.

The time elapsed between the time of complete perforation and operation was respectively eight hours, seventeen hours, and one hour.

In cases I and III there was probably leaking of the ulcer before the flooding of the abdomen took place. In Case I this occurred twice, thirty-six and twelve hours before, while in Case III it occurred three days, and four hours before the flooding of the whole abdomen.

A gastro-enterostomy was made in all three cases, in Case I with a Murphy button, in case II and III by simple suture. In Case I I believe that the Murphy button was the cause of the second and third perforations. With the poor general condition of the patient and the condition of the secretions which brought about the original perforation, I believe that the presence of the button caused sufficient injury to the mucous membrane to start the second and third ulcers, which were at the lower part of the stomach in the region in which the button was found. I could certainly never use the button again in such an operation.

Anterior gastro-enterostomy was made on Case I, while the posterior method with a short loop (Moyuahan) was used in cases II and III.

All three cases recovered from the immediate effects of the operation, but case I died in three weeks of exhaustion as a result of the second and third perforations.

Case II gained 44 pounds between November and February and is in excellent health at this time, October, 1905.

Case III has been perfectly well ever since the operation and has no gastric symptoms whatever. He is in excellent health at present, October, 1905.

SHOES AND FEET.

BY ROBERT ROUTTER, M.D.,

Junior Assistant Surgeon Children's Hospital, Boston.

SINGLE or incomplete ideas given to a shoemaker make him build his shoe accordingly, only to find himself left with a stock for which there is no market. One company made Thomas heels and greatly advertised them, but doctors did not appreciate it. Another firm finding that arch supports are essential to all feet has gone to considerable trouble to make steel shanks right and left. (Fig. 1.) Shanks are usually made of flat steel cut from the sheet. This company made

FIG. 1.

FIG. 2.

FIG. 1.—A, the vamp seam which will not stretch. B, the counter which grips the os calcis. C, the shank of the shoe. D, the steel shank.

FIG. 2.—A, shoes, front view of a bad position of the ankle astragalo calcaneus valgus and abduction of the front of the foot. B, posterior view of the same.

two shanks, one curved for the left arch and the other for the right. Unfortunately the shank was placed under the outside of the foot. Another firm made a last, secured the indorsement of a number of doctors in Boston and in New York. The shoemaker advertised this broadcast, threw away the last and still sells shoes using the same advertisement. At present the shoemaker is afraid to follow shoe ideas as doctors have not been sufficiently agreed to insure a market for good shoes. On the other hand if the physician indorses a shoe, as soon as the market is assured the shoemaker may make whatever he likes and give the counterfeit to the customer. Ingenious methods have been devised and elaborate agreements signed to hold a shoe factory to a patent. The shoemaker dodges these patents and uses the stamp as if the patent was employed. Shoemaking is difficult to understand. Asking for one point changed on a shoe alters the mechanics of the shoe in a way that can be foreseen only by the experienced shoemaker. Orthopedic lines may give atrocious wrinkles.

Take the foot of an adult or of a child which has worn no shoe or else well-fitting sandals for

several months. If the feet in question are not deformed, such feet will have no pressure marks except on the sole and no areas of congested skin. The appearance of the skin and feeling of the tissues on the dorsum is that of a healthy exercised hand. A young woman takes off her shoes and stockings. Her feet never touch the floor excepting in shoes or slippers. The foot is delicate, atrophied, the toes pressed together and the phalangeal joints flexed. The outline of each toe is impressed deeply into the sides of the next; there are small calluses on the sides and sole of the foot and on the toes and under side of the toes. In an inactive person the foot is pale and cold; there may be pressure marks which, by the way, are not necessarily painful. On the other hand, in an active or plethoric person such a foot is blue or purple in areas due to the congested superficial circulation and the pressure marks are more evident and may remain some time after the shoe is removed. The foot has been gradually distorted by the shoe pressure.

A very large proportion of trouble with feet is caused by shoes. The best shoe that can be bought will affect the foot to a more or less degree. What can be done to prevent these marks of abuse which, when age comes on, makes walking such a burden?

Notice on the street how few people walk unconsistently of their feet and how many awkwardly because of shoes. The relation of the foot and leg in carrying the body weight is important. The internal malleolus should not be prominent. In other words, there should not be an astragalo calcaneus valgus. (Fig. 2.) The weight transmitted through the tibia should, if the line is prolonged, stick well to the outer side of the foot and under the anterior position of the os calcis. Do what you will to the foot you cannot right its faults until the weight bearing is advantageously placed. Next, the front part of the foot should be slightly adducted. In a stiff foot these positions will take the ball of the great toe off of the floor. The foot will limber up in time or appropriate treatment for this purpose can be applied. In action the front foot is often markedly adducted, especially in running, and flexibility in this direction is desirable. When the shoe makes this impossible there is marked restraint and loss of power resulting later in weakness and stiffness. The foot should be made flexible and its muscular tone improved; plates avoided and used only by the surgeon with the understanding that they will limit the motion. The shoe should be flexible. Heavy and stiff soles should be avoided. The front part of the foot and the toes must be allowed freedom of motion and not be compressed by the upper or vamp seam. The calf muscles must not be shortened nor the tendo-Achilles pressed on by the counter or its seam. This pressure can produce considerable tenosynovitis.

Having placed the weight advantageously, made the foot flexible and strong and given the toes freedom of motion, select a shoe that does as little harm as possible. Shoemakers make shoes primarily to sell. The fashion of the shoe

is based on lines selected in the ages when natural types were avoided. The fashionable high heeled shoe is as far from the natural outline as the tight-laced figure is from the ideal Greek figure. (Fig. 3.) Women have discarded tight lacing of

FIG. 3. — This shoe causes the flexion of the toes and slides the foot into the narrow space for the toes.

the chest and to some extent of the waist. Physical outlines are becoming more admired. It will not be long before tight shoes and toeing out will be superseded by a natural shaped shoe and straight gait.

To prescribe a shoe with an adducted front part seems simple. In comparing lasts one shoe that seemed at first to be in good line anteriorly was practically the same as another which seemed not as good, the difference being due to a clever optical illusion practiced by the shoemaker. (Fig. 4.) This consisted in curving the inner line of the shank and the anterior line of the heel so that they seemed different until the two soles were traced on paper and the tracings superimposed.

FIG. 4.

FIG. 5.

FIG. 4. — B is a shoe having neither right nor left. A is the same shoe with the optical illusion from the cut of shank leather and anterior line of heel.

FIG. 5. — There should be room at B in the upper, the sole may curve in.

A shoe with room (at *b*, Fig. 5) on the outer side of the shank over the cuboid will not necessarily be lacking in this if the sole does not show it. In other words the upper must be considered as well as the sole.

The chief fault of the present method of shoe making is that the shoe is made for an astragalo calcaneus valgus. (See Fig. 2.) It is impossible to adduct the front of the foot satisfactorily or get a good line of the great toe until this is corrected. Shoemakers cannot be expected to get a really trig shoe on orthopedic lines until this fault is overcome in the patient as well as in the shoe. This year the heel on the outside is as high or higher than the inside. The shoe curves in just anterior to the outer side of the heel and there is a wide sole on the outer side causing abduction of the front of the foot. (Fig. 6.) The counter is long and grips the os calcis throwing its anterior part in and its upper part over in-

ward. (Fig. 7.) Both these factors produce astragalo calcaneus of medio tarsal valgus and aggravates any tendency to hallux valgus or to flat foot. Then again, the toes are pressed together or into each other so that the toes have angular outlines and depressions, some toes often overriding the others, and the toes are flexed and cramped. (Fig. 8.) The semi-condition of hammer toe is bad enough, but in addition the first phalanges become, one or all, almost perpendicular, or at an angle of forty-five degrees flexion on the metatarsals causing calluses under the ball of the foot, and perhaps this is one of the prominent factors in producing Morton's disease. (Fig. 9.)

This dorsal flexion of the first phalanx on the metatarsals is a serious condition and should be corrected before it is advanced and before the joints become stiff. It is present to some degree

FIG. 6. — Showing the broad outward curve causing abduction of the front part of the foot and the inward thrust at B, on the outside of the shoe.

in the majority of anterior arch cases. In the milder ones it occurs only when the shoe is on; in the worst cases the extensor tendons are shortened and the cure is made correspondingly difficult. (Fig. 10.) Many people cannot move their toes with any degree of proficiency. Their toe joints and muscles are unused and the stiff condition results so gradually that there is no discomfort in the process. The dorsally flexed first phalanx and hammer toe is not only caused by the pinching and over-riding of the toes and by forcing the foot forward into a narrow-toed shoe in walking, but the high heel pushes it forward and also, by raising the tarsus and metatarsal, increases the position of dorsal flexion of the phalanges. (Figs. 11 and 12.) The shank being stiff and meeting the sole at an angle acts as a splint and the unyielding vamp seam with

FIG. 7. — Showing the counter C. A is the outer side of the foot. B, the inner side, the heel is displaced laterally outward and raised on the outside by the shoemaker.

every step forces the first phalanx into dorsal flexion.

The sole under the ball of the foot besides failing to follow the lines of a slightly adducted and weight-balanced foot is made up on the sides of the double thicknesses of the upper and the lining. (Fig. 13.) This causes a gap or air space

between the inner and outer sole. B, which is sometimes filled in an imperfect way with ground cork or leather, and more often left unfilled. As a result the foot is held up at the sides and falls in the middle. This is one cause of anterior arch troubles. (Fig. 14.) The lumping of the upper and upper lining where they are stitched acts as a

pad under the posterior part of the os calcis and tends to tilt and flatten the arch of the foot (Fig. 15), and with a high heel to shorten the tendo-Achilles.

The faults of too long a counter, stiff uppers, hard toe caps, the counter squeezing the foot forward and the incurve of the shoe gripping the Achilles tendon are all worthy of consideration.

FIG. 10.

FIG. 10.—Front view of an extreme case of the same. These toes cannot be made to touch the floor.

FIG. 11.—Flexion of the toes by a high heel, tight vamp seam at A and a long steel shank at B.

If you make a shoe flexible in adduction and in dorsal flexion the heel must be made higher on the inner side so that it will not wear here; otherwise the flexible shank will cause the shoe to slump. This is true as long as heels are used. If the shank is omitted, therefore, something must be substituted, some mechanical device to prevent the shoe from slumping unless the heel is abol-

FIG. 12.

FIG. 13.

FIG. 12.—Showing the thrust forward against the tight vamp seam A.

FIG. 13.—Diagrammatic cross section of the front of a shoe. A—space for foot, B, dead space between the sole and inner sole caused by the lumping at the sides of the upper D, and the lining C.

ished or made almost nothing. The best substitute is a slanting heel, high at the inner and anterior part and sloping back and outward.

To summarize briefly the desirable points of

the foot and the qualities of the shoe that effects them: First,

The factors that interfere with a good position of the internal malleolus or advantageous weight bearing are: The heel higher on the outside, the stiff shank and tight vamp seam combined, the slanting and long stiff counter and the placing of the heel on the outer side of the shoe.

A good line of the great toe is interfered with by a tight shoe cramping the toes, by anything that causes abduction of the front of the foot, by anything that produces valgus at the astragalous calcaneus articulation, by heel slanting inward, by the shank being stiff and combined with a tight vamp seam and by a tight upper.

Proper play of the toes is limited by the width of the front part of the shoe, by a tight vamp

FIG. 14.

FIG. 15.

FIG. 14.—Showing the sagging of the inner sole and the way the sides of the foot are forced up at the sides. A, foot, B, sole, C, inner sole.

FIG. 15.—A, the lumping of the lining counter, counter lining and the upper under the posterior part of the os calcis.

seam and a stiff shank, by a tight upper, by a high heel, by a thick sole and by a stiff upper.

Adduction of the front foot and flexibility in this direction is limited by the high outer side of the shoe, by the high heel higher on the outer side, by too tight a counter and by lack of fullness over the cuboid.

Flexion of the first phalanges on the metatarsal may be caused by pinching the toes, by a high heel, by angular steel shanks, by dead space between the sole and inner sole and by a tight vamp seam and stiff shank.

In order to make the foot admired it must be held in a position of strength, have the appearance of health and be free from signs of abuse. This brings up the point of the wearer who, in a measure, should be considered. What he will wear when his feet are lame he will not when they are well until public opinion allows that good feet are better than French shaped shoes. For those whose feet are not yet lame, by correcting the worst faults of shoes and allowing the lesser ones to remain for the present, some sense may be smuggled in with the shoes and the unsuspecting customer be spared a future visit to the office.

DAZZLING HEALTH STATISTICS.

BY THOMAS J. MAYS, M.D., PHILADELPHIA.

The value or the worthlessness of a proposition is determined not by its promises, but by its performances. In the light of this criterion let us see where some of the phases of the contagion theory of consumption stand. It may be said that he who in the absence of a full knowledge of this doctrine studies most of its recent literature will probably conclude that if this disease is not

already "wiped out" through its instrumentality, it is so near that point that only a short time is required to complete this task. No Sellenian eloquence has ever extolled and magnified the virtues of any remedy with greater skill than that which is made use of in exploiting the specific value of the bacillus theory as a means of annihilating pulmonary consumption.

In 1892 Dr. Lawrence Flick of Philadelphia, one of the pioneer devotees of this theory, contributed a paper to *The Medical News* for May 14, 1892, in which he claims that owing to the conversion of the medical profession of this city to the notion that consumption spreads through dried consumptive expectoration, and that in consequence of the care which was taken in at once destroying this contagious matter, 784 lives had been saved annually to this city from 1882 to 1891.

Whether the medical profession of Philadelphia has been converted to the contagion theory is, perhaps, not very easy to determine, but it is not difficult to demonstrate that the saving of 7,840 lives from consumption in ten years by means of bacillary devices, or by any other influence, is a fantastical misconception and is based on a strange and remarkable twisting of the plain meaning of recorded facts.

Any one who will take the trouble of looking up the health records of Philadelphia will find that the deaths from consumption, instead of decreasing 7,840 in number from 1882 to 1891, as stated by Dr. Flick, only diminished 640 in number, or 64 a year, while the population increased 22% during the same time. Is even this small decrease traceable to any such plans of prevention as are designated by Dr. Flick? Hardly. For if this was the true cause, its influence must have been greatly nullified in the following decade, since from 1891 to 1901, the decline of this disease numbered only 471, or about 43 a year, while the population increased 23% in that time. It is, therefore, beyond the bounds of ordinary reason to conceive the nature of the transcendent mathematical methods which are made to figure out how 7,840 people were saved from consumptive graves in Philadelphia in ten years from 1881 to 1891, when actually there was only an average annual decrease of 64 deaths during that period. A diminution of 784 consumptive deaths in a year would necessarily wipe out this disease in Philadelphia in less than four years, yet statistics show that it is nearly as fatal at present as it has been for the last decade and a half.

Equally extravagant and misleading is the declaration¹ of Dr. Hermann M. Biggs, medical officer of the New York Health Department, that at least twenty thousand lives have been saved from consumption in New York City from 1886, when registration and disinfection measures were first legally introduced for the suppression of this disease, to the year 1901. This means an average annual reduction of 1,333 consumptive deaths from an average of about 5,000 yearly deaths

during this period. On referring to the health statistics of old New York City, i. e., the boroughs of Manhattan and the Bronx, it will be found that from 1886 to 1901 the population increased 45%, and that instead of saving 20,000 persons from consumptive graves, as stated by Dr. Biggs, there is an actual total reduction of about 2,500 deaths from this disease, or about 150 a year during that time. (The fact that Greater New York was formed in 1898 does not alter these figures very relatively, since the old New York statistics cover the period here surveyed, except the four years from 1898 to 1901.) Almost identical results are obtained, if the increase of population and the increase of consumption are calculated from year to year, or from the beginning and the ending of this period. As has been shown to be the case in Philadelphia, most of this decrease occurs in the early and not in the later part of this period, and gives evidence, therefore, that the virtue of disinfection and registration, if any such exists, has declined materially in recent years. Furthermore, the absurdity of the statement that consumption decreases to the extent of 1,333 deaths a year becomes very obvious when we consider that such a rapid reduction rate would have totally destroyed consumption in New York City in about four years, or as long ago as 1890, yet statistics of the New York Health returns point out that the annual average of about five thousand deaths have occurred from this disease in old New York from 1890 to 1901.

These are some of the statistical obsessions that have helped to force the conviction on many minds that consumption is conveyed from the sick to the well by means of the tubercle bacillus, and that all that is necessary to destroy this disease in a single generation, as has been asserted over and over again, is to use scrupulous care in keeping apart the sick and their expectoration from the well, and to fumigate and disinfect the surroundings of the former. In and out of season we hear of the recent fabulous reduction in the consumption rate of New York and Philadelphia since fumigation and disinfection were installed, and of the claim that what is possible in these places is applicable everywhere, and that results will amply demonstrate that the remaining deaths "are to a very great extent unnecessary." Lightning arguments of this kind have had the effect of sowing widespread misapprehension and demoralization among the laity in regard to the danger of this disease. Social and family relations have been greatly disturbed in consequence. No employee who is suspected of having consumption is safe in his position to-day, no matter how capable he may be to perform his work. Hotels, boarding houses, and even health resorts close their doors against such invalids. Several State Boards of Health in this free country of ours refuse to employ teachers who are affected with this disease, and many hundreds have been dismissed or refused employment. Children who cough and expectorate are debarred from attending the schools of one of these states. It is stated on reliable authority that consumptive employees

¹New Tuberculosis, Its Cause and Prevention, published by the Committee on the Prevention of Tuberculosis of the Charity Organization Society of New York City.

in the government service at Washington are dismissed, and that a Pennsylvania town makes the regulation that barbers shall not shave consumptives. The Board of Health of Jersey City recently adopted a resolution refusing the accommodations of the public waiting rooms and passageways of the ferry buildings to traveling consumptives, compelling the providing of special cars for the transportation of such passengers, and ordering thorough fumigation and disinfection under the direction and supervision of the Board of all cars or trains used for this purpose.

One may smile at such matchless senility, but what is to be thought of those who furnish the foundation on which such schemes of folly are erected? Is it not the work of the germ theorists who for years have dinned into the ear of the people that this disease depends solely on communication between the consumptive and the healthy that is responsible for this public sentiment? Under these circumstances what can the laity, who form not an unimportant part in molding and in composing the membership of our health boards, be expected to know? Do they know that the germ origin of consumption is contrary to the plain dictates of medical experience? Do they know that with a few unimportant exceptions, not an author who has written a special work on this disease, either in the English or the German language, unqualifiedly indorses this theory? Do they know that the germ theorists base the contagion theory of this disease on animal experiments, that when they find a certain fact in the experimental animal they at once reason backwards and conclude that because this is true in the latter it *must* be true in the human subject—thus actually treating this whole question largely as if it related to veterinary and not to human medicine? Is it any wonder that under perverted leadership during the last ten or fifteen years, pulmonary consumption has latterly increased in Philadelphia and New York cities? and that, on the whole, the practical results of the treatment of this disease are not better, if as good, as they were twenty or thirty years ago?

Medical Progress.

RECENT PROGRESS IN LARYNGOLOGY.

BY A. COOLIDGE, JR., M.D., BOSTON.

MANUEL GARCIA.

A NOTABLE event during the past year was the celebration of the one hundredth birthday of Manuel Garcia, who fifty years ago laid the foundations of modern laryngology. Although a few attempts, more or less successful, had been made in previous years to see the glottis, to Garcia belongs the credit of introducing the practical use of mirrors to see and study the larynx. An interesting paper by Farlow, written at the time of the Garcia celebration and containing the early history of the laryngoscope, appeared in this JOURNAL of April 20. It is truly a unique

occasion, when a man, who at the age of fifty inaugurates a technique which develops into an important specialty lives to celebrate his hundredth birthday surrounded by men from all parts of the world who have made themselves known through this special work. Garcia was born in Spain so long ago that he was obliged to leave the country owing to the advance of Wellington's army in the Peninsular War. His father and sister were well known operatic singers, and he started in life in the same vocation, appearing in opera in New York eighty years ago. He soon afterwards left the stage and devoted the rest of his active life to teaching music, at first in Paris, later in London. His interest in the larynx was therefore confined to its physiology, especially with reference to tone production. The birthday celebration took place in London. He was received by the king, and entertained at a banquet at which more than four hundred guests took part. He received addresses and messages from all over the world and was presented with a picture of himself by Sargent. Not the least interesting point in connection with this celebration is the fact that it was also the fiftieth anniversary of the introduction of the laryngoscope.

THE SUBMUCOUS OPERATION FOR DEFLECTION OF THE NASAL SEPTUM.

During the past year this operation has been the subject of several papers which, without introducing anything essentially different from the methods of the few preceding years, contain many interesting details of technique and instruments. Killian¹ describes his operation in detail in a paper which should be carefully studied. He considers that the essential feature of his technique is the use of his long specula. After the mucous membrane has been separated from both sides of the septum the speculum is passed through the incision in the mucous membrane, and one blade through the incision in the cartilage also. The blades then have the denuded septum between them, in a median space between the two septal mucous membranes. By opening the speculum this space becomes large enough to give ample room for the removal of as much cartilage and bone as is necessary.

A description of the operation by Freer appeared in this JOURNAL a year ago.² Another comprehensive paper by the same author³ describes not only his own methods, but also reviews the details of the operations of others. He advises the older form of incision through the mucous membrane, two cuts at right angles to each other over the angles of deflection, in preference to the single anterior incision of Killian, Hajek and others. Among his interesting conclusions may be mentioned the following: the operation is adapted to children, but the chance of a possible recurrence from the effect of growth demands a very complete removal of the deflection. The firmness, and, therefore,

¹ Archiv. fur Laryngol., Bd. 16 Heft. 2. Translated by Foster. Annals Otol., Rhinol. & Laryngol., June, 1905.

² Boston Medical & Surgical Journal, Feb. 2, 1905.

³ Transac. Amer. Laryngol. Assn., 1905. Annals Otol., Rhinol. and Laryngol., June, 1905.

probably the cartilage and bone of the septum, is completely or nearly completely reproduced in the window after the resection. The lower portion of the quadrangular cartilage, as high as the level of the ala nasi, may be resected without fear, from its anterior inferior free border horizontally back to the bone. The recumbent position of the patient is best for the operation, except in operating along the nasal floor. The presence of a nasal angle in an instrument complicates its movements, and makes it necessary to hold it with a stiff wrist and fingers, thus sacrificing the lightness and accuracy of motion of straight instruments. With the exception of fragments cut with the chisel from the crista incisiva or anterior end of the vomer, neither cartilage nor bone should ever be broken, twisted or torn from its attachment, but should be cleanly cut away. Sewing is needless; strips of lint impregnated with sublimate of bismuth makes the best tampon. The author introduces the strips in layers by which the flaps are perfectly held in place.

Ballenger⁴ has introduced an ingenious knife in which a stirrup blade swings as a swivel between the tips of two prongs. The prongs are placed astride of the denuded cartilage which is cut by the blade as the prong tips describe the outline of the cartilage to be removed. As much cartilage as is desired is thus quickly removed in one piece.

A modification of the incision through the mucous membrane is described by Yankauer.⁵ A single vertical incision is made so that its lower end corresponds with the anterior edge of the nasal floor. It is then continued outward on the floor of the nose half way to the ala, and the mucous membrane, perichondrium and periosteum are separated and reflected outward upon the outer nasal wall. This gives a large amount of room for subsequent work.

NASAL DIPHTHERIA AND OPERATIONS.

The fact that the bacillus of diphtheria may exist in the nose unsuspected should be constantly borne in mind, and especially before beginning any operation in the throat in children. From his large experience in diphtheria McCollom⁶ concludes that many serious outbreaks are due to the fact that some member of a family or inmate of some institution has had a profuse discharge from the nose without any constitutional disturbance and has been the focus from which has arisen many severe cases of diphtheria. This is not a theoretical statement, but is the result of experience. Every profuse discharge from the nose, particularly if there is any excretion about the nostrils, should be looked upon with suspicion and cultures should be taken. If adenoids are to be removed, cultures should always be taken before the operation is performed, for it sometimes happens that a child who has a profuse discharge from the nose, immediately after the removal of adenoids or the ablation of the tonsils, has a severe attack of diphtheria. If

the operation for cleft palate is to be performed, it is still more important to take cultures; because if there are any bacilli of diphtheria in the nasal discharge, this organism is sure to grow upon the cut surfaces of the operative tract, and the patient not only has an attack of diphtheria which may be mild or severe, but also the edges of the wound slough and render a second operation much more difficult.

The whole subject of latent diphtheria and the varying forms of diphtheria bacilli is of the greatest importance in connection with the health and oversight of children. A paper by P. Watson Williams⁷ offers an excellent summary of these questions. A nasal catarrh, increased pulse frequency, an irritable heart, a redness of the fauces, or slight tonsillitis, may severally be the only symptoms, and yet, if due to diphtheritic infection, it is pathologically diphtheria. But the presence of virulent diphtheria organisms in the nose and throat, unassociated with any local or tissue changes, is not diphtheria, although in recent contacts such inoculations may rapidly pass into diphtheritic infection. The diphtheria organism is not only exceedingly polymorphic but variable in its virulence, from the highest virulence to absolute nonvirulence, while the susceptibility of the host likewise varies within wide limits.

THE DEVELOPMENT OF THE ACCESSORY SINUSES.

From the study of skulls of the fetus and infants and from a review of the literature of the subject Collin⁸ makes the following deductions: But two of the accessory sinuses are present at birth, — the ethmoidal cells and the maxillary antrum; the antrum does not in infancy occupy the same relative position in regard to the orbit as in later life, and cannot be reached or entered by the usual methods; neither can this be done nor satisfactory drainage effected until after the descent of the second or permanent teeth without the destruction of a tooth socket. It makes impossible also the intral route to the ethmoid and sphenoidal sinuses during this period of life. The sphenoidal sinus makes its appearance shortly after birth and may be found as a distinct cavity as early as the end of the first year. Practically, however, it may be considered as the most posterior of the posterior ethmoid cells. The frontal sinus is not present at birth. It appears first in the orbital plate of the frontal bone between the end of the first and the beginning of the third year. Practically at this time it is the most anterior of the anterior ethmoidal cells; it may be seen in the vertical portion as early as the end of the third year. This is early, however, at its appearance in the vertical portion should be put down from the third to the sixth or seventh year.

RADICAL OPERATION OF THE FRONTAL SINUS.

A series of papers on the diseases of the accessory sinuses, with the discussion of the anatomy of the sinuses, appeared in the *Transactions of the American Laryngological*

⁴ *Annals Otol., etc.*, June, 1905.

⁵ *American Journal of Surgery*, June, 1905.

⁶ *Laryngoscope*, Sept., 1905.

⁷ *Journ. Laryng. & Rhinol.*, July 1, 1905.

⁸ *Am. Journ. Med. Sciences*, Feb., 1905.

logical Association for 1905,"⁹ and represents very well present views and differences of opinion, especially as held in America. In relation to the frontal sinus the impetus to radical operation by the introduction of the operative methods of Ogston, Luc, Kuhnt, Jansen and Killian, a few years ago, has stimulated study of and attention to this cavity. In this country Coakley has established a method of proceeding which makes a summary of his experience interesting and timely. In acute disease urgent symptoms demand radical treatment, but these cases are fortunately rare. Chronic suppuration is practically always associated with suppurative in some of the neighboring cavities. A radical operation is indicated in the following conditions: Chronic suppurative frontal sinusitis accompanied by multiple polyp formation in the nose, associated with ethmoiditis, if the patient desires to be permanently rid of the disease. In severe acute exacerbations of the chronic condition. If intranasal treatment does not suffice to prevent the discharge from passing into the antrum and the odor and taste of the fetid discharge from the latter annoy the patient, then, in order to cure the antrum, the frontal must be operated upon radically. Very large frontal sinuses with multiple septa, and particularly those with recesses extending backwards over the roof of the orbit, can be but imperfectly irrigated. Until recently we have had no means of ascertaining these facts. Skiagraphy, however, as now practiced will give us the exact height and breadth of the frontal sinus, indicate the number and position of the septa and in many cases inform us of the presence of an orbital recess. The radical operation should be advised for such patients. When the drainage is poor and headaches frequent, these patients generally submit to a radical operation. Intranasal treatment is slow and the results uncertain. A radical operation may take as long to effect a cure but this, when obtained, is permanent. The neurasthenic patient who is prostrated each time intranasal treatment is attempted, and rarely submits to enough being done at one time to make much progress, is more satisfactorily treated by the radical method. If a fistula has formed leading into a frontal sinus a radical operation is the only treatment likely to effect a cure.

The Ogston-Luc operation consists in opening the anterior wall of the sinus, imperfectly curetting the mucous membrane, dilating the naso-frontal duct, usually inserting a rubber drainage tube through the latter into the nose for a few days, sewing up the frontal wound and trusting that the better nasal drainage will eventually result in establishing a cure. Kuhnt removed the entire anterior wall of the frontal sinus, eviscerated the entire mucous membrane in the cavity, naso-frontal duct and adjacent ethmoidal cells, sewed up the skin wound and placed drainage from the bottom of the wound into the nose.

Coakley's experience with the mastoid led him to believe that it might be possible to treat a frontal sinus like a mastoid, *i. e.*, to operate in the

manner of Kuhnt but to pack the frontal sinus and naso-frontal duct so that the granulations would spring up and first occlude the narrowest part of the cavity, the bottom of the naso-frontal duct. This having been accomplished the condition would be the same as in the mastoid wound after the closure by granulations of the aditus and antrum, and it would be merely a matter of time for the upper part of the frontal sinus to fill with granulations and become completely obliterated. There is, of course, some deformity depending on the size of the cavity. If the operation is properly done there is no greater danger of recurrence than in a mastoid. He has operated upon more than a hundred cases by this method and has found the results very satisfactory.

(To be continued.)

Reports of Societies.

THE MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

STATED MEETING, DEC. 11, 1905.

SYMPOSIUM ON PNEUMONIA.

The introductory was made by the President, DR. T. E. SATTERTHWAITE, who said in part: "Inquiring into the cause of the disease, have we one, or several, etiological factors? Other questions that suggest themselves are, What is the relation borne by pneumonia to occupation, the season of the year, age and social conditions? Even in plain lobar pneumonia have we discovered that there is but a single infecting agent? Another question is as to the limitation of the disease. Is it self-limited, and, if not, what are the remedial agencies which are specially applicable to the different forms of the affection? How much may we expect from massive doses of mercurials, the application of heat or cold, inhalations, quinine, salicylates or creosote, etc.?"

DR. J. M. ANDERS of Philadelphia read a paper on

THE PROPHYLAXIS OF LOBAR PNEUMONIA.

Although, he said, the natural methods of diffusion of the pneumococcus are imperfectly known, the report of the Medical Commission for the Investigation of Acute Respiratory Diseases of the Health Department of New York contains the results of investigations which tend to throw fresh light on this important problem. Until the present, purely empirical prophylactic measures have been for the most part advised and more or less generally employed. The results of experimental studies on the pneumococcus, carried out under the direction of Drs. William H. Park and A. W. Williams, have confirmed the opinion previously held by most authors that pneumonia should be considered to a certain degree as contagious. Another fact indicated by these researches is that the virulence of the pneumococcus may be rapidly increased for a susceptible species of experimental animal by successive passage. It is generally believed that the principal source of the causative organism is the sputum of pneumonia patients, but since the virulence of the pneumococcus may be quickly increased, as shown by the investigations of Park and Williams, and since the organism is quite prevalent in normal sputum, the latter source must also be reckoned with in considering measures of prophylaxis. It is gratify-

⁹ Laryngoscope, August, 1905.

ing to observe that the Commissioner of Health of New York has issued a drastic edict against spitting on the sidewalks, and that already a decrease in the number of cases of pulmonary tuberculosis has been noted in certain districts in which the law has been enforced. What is true of consumption applies with equal force to lobar pneumonia, since the itinerant cases of the former find their counterpart in well persons, or those suffering from catarrhal conditions of the respiratory tract, who harbor the pneumococcus. The conclusions arrived at in the paper were as follows:

(1) Certain degenerative lesions, especially of the cardio-vascular system and the kidneys, have shown an increased incidence during the last two decades, and these are found to be associated or antecedent conditions in many cases of pneumonia; hence are probably potent predisposing factors. (2) The indoor conditions during the cold season favor multiplication and propagation of the pneumococcus, and at the same time tend to diminish resistance to infection by the specific organism. (3) The aged are peculiarly susceptible to pneumococcus infection; hence their bodies should be kept as strong and healthy as possible, especially during the pneumonia season. (4) To overcome the predominating factors in individual predisposition, special attention must be paid to the subject of ventilation, to appropriate clothing, and to the avoidance of agencies which cause degeneration of the heart, vascular system and kidneys, as alcohol, social excesses, an over-strenuous business or professional life and the like. (5) The sputum is the principal source of infection, and should be thoroughly disinfected as soon as expectorated, and then destroyed by burning. Public expectoration should be restricted in every possible manner. (6) A large proportion of the general populace harbors the pneumococcus in the naso-pharynx, and this is especially true in families and institutions in which cases of pneumonia have occurred. Hence thorough cleanliness and disinfection of these chambers should be carried out during the pneumonia season, and more particularly in the case of persons more or less exposed to the virus of the disease. (7) Means to prevent dust from accumulating and its daily removal from the home and the city streets are imperatively demanded. (8) Public health authorities should be given full executive power to carry out rules and regulations relative to pneumonia, looking to the prevention of its spread, as in the case of other infections and contagious diseases. They should also carry on a campaign of public education. (9) Measures of prophylaxis must accord with intelligent public opinion before they can be rendered wholly efficient either by municipal or private authority.

DR. R. W. WILCOX spoke on

SOME QUESTIONS IN DIAGNOSIS.

After alluding to certain points which might lead to the recognition of the disease before the characteristic physical signs were developed, he said that fortunately in many atypical cases, modern methods had enabled us to differentiate pneumonia from other diseases. Thus, when a case had extended beyond the regular period of pneumonia, and the question arose whether typhoid fever might not be present, the use of the Widal reaction would usually determine the matter. During epidemics of cerebro-spinal meningitis there were certain cases in which the disease seemed to spend its force on the lungs. Here the examination of the fluid removed by lumbar puncture would show the true nature of the affection present.

DR. H. P. LOOMIS read a paper on

THE PRESENT TREATMENT OF PNEUMONIA AS EXEMPLIFIED BY THE ROUTINE TREATMENT OF THE DISEASE IN FOUR OF THE LARGE NEW YORK HOSPITALS.

The four hospitals are Bellevue, Roosevelt, the New York and the Presbyterian. In all of them calomel, usually in small, repeated doses and followed by a saline is given the patient on admission, and the calomel is repeated during the course of the disease, if necessary. Local applications to the chest are made only when the pain and distress are intense. In the New York and Bellevue ice poultices are sometimes used. During the height of the disease milk is given exclusively or as the principal article of diet, and at Roosevelt patients are urged to drink water largely. The treatment of fever varies more than anything else, although a temperature of 104 or over is not necessarily regarded as an indication for special treatment. Cold packs to the anterior portion of the chest, tepid sponges and alcohol sponges are variously used. Tub baths are never given at Bellevue or Roosevelt; at the New York, very seldom; and at the Presbyterian, only in alcoholic cases with nervous symptoms. Codeine and heroine are the principal drugs employed to control cough, and trianol, veronal and codeine for insomnia. Pulmonary edema is treated by cupping and hypodermic injections of adrenalin or atropine, together with increased stimulation. Oxygen is not given as much as formerly in any of the hospitals. The three cardiac stimulants which are used in all are alcohol, strychnine and digitalis. At the Presbyterian Hospital alcohol is employed less generally than formerly; in the other three quite as much as it was two or three years ago. Nitroglycerin is used only very occasionally. During the past year or so a number of drugs have been tried and discarded, as potassium iodide, salicylates and pneumococcus serum. Creosote is still sometimes given, especially at Roosevelt and the Presbyterian, but the staff of these hospitals state that they can see no results from its use. At Roosevelt saline injections into the rectum are employed, especially in alcoholic cases and those where nutrition is failing.

DR. HOWARD A. HAIN of Philadelphia read a paper on

THE TREATMENT OF PNEUMONIA.

In it he especially urged that remedies be administered only when very definite and clear indications for their use were present. In many instances, spurred on by the anxiety of friends, the physician is inclined to give medicines continually throughout the entire course of an attack of croupous pneumonia, forgetting that remedies which are powerful enough to do good may, under certain circumstances, be powerful enough to do harm. Further, it must be recognized that our means of treatment cannot be curative, and should be directed simply to the support of the system, and the regulation of its functions, until the disease has run its course. In many instances rapidly-acting, but fleeting, circulatory stimulants, such as Hoffmann's anodyne and aromatic spirit of ammonia, are all that are needed to bridge over temporary periods of depression. These remedies are not advantageous when used for a long period of time, as they lose their effects and are apt to disorder the stomach. If digitalis is employed, it should always be in the form of a preparation which has been physiologically tested, since other specimens of digitalis often vary greatly in their pharmacological activity. Of the remedies which are best for the combating of collapse and circulatory failure, strychnine and atropine undoubtedly rank highest, the atropine being particularly valuable in those cases in which

there is a gaseous pulse with relaxed blood vessels. Digitalis often fails because the heart muscle has undergone degeneration as a result of the toxemia, or because the high temperature of the disease prevents it from exercising its physiological properties. Mild alkaline diuretics, for the purpose of flushing the kidneys, are useful, and hypodermoclysis may at times be a valuable resource. In conclusion, the author once more urged upon his hearers the necessity of avoiding medication except in the presence of very direct indications for the use of certain drugs. But, on the other hand, he advocated the free administration of remedies which were indicated to meet special conditions arising in the course of the disease. While, on the one hand, we must not be too active, it is an equally great mistake to be unduly passive in the presence of such a grave illness. Nitroglycerin, often used in pneumonia as a cardiac stimulant, is always abused under such circumstances, since it is a circulatory relaxant, and never active as a true stimulant. This is a point overlooked by many members of the profession. The only indication for the employment of nitroglycerin in pneumonia is when the arterial tension is unduly high, and the heart is consequently called upon to do an excessive amount of work.

DR. J. MADISON TAYLOR of Philadelphia read a paper on

THE ROLE OF SALINE SOLUTIONS IN THE TREATMENT OF PNEUMONIA.

He presented a *résumé* of the facts relating to the disposition of the normal salts of the blood plasma and its contained autoprotective potentialities, a recognition and use of which is capable of furnishing a beneficial agency in overcoming infectious processes. A few observers have called attention to the value of saline solution designed to supply the enormous loss in these essential constituents of the plasma which occurs during febrile states. These, however, have recommended the use of the measure only late in the disorder and in desperate cases. Dr. Taylor urged the extreme importance of following the advice of Sajous to employ it as soon as the character of the disease is recognized, in order to insure the full efficiency of the blood's antibodies, *i. e.*, the body's autoprotective powers. Saline solution, used early, preserves the blood's normal fluidity, renders normal osmosis possible, and gives free sway to the immunizing process. He believes that to delay in the use of salines is just as dangerous as to delay administering antitoxin in a case of diphtheria, and, moreover, that in infections the blood suffers such rapid depletion of saline elements (the effect of which is to impair the efficiency and finally arrest the protective functions of the organism) that this constitutes one of the most active causes of death. His practical recommendation was to begin at the outset, in pneumonia and other infectious fevers, the internal use of saline solution, especially containing sodium chloride and the other saline constituents of the blood. The use of these salines by hypodermoclysis or enteroclysis has been recently shown by a number of observers, acting upon Sajous' recommendation, to be of great efficiency when begun early. The employment of the saline drink has been shown by Todd and by Dr. Taylor to be of equal efficiency and not at all inconvenient or disagreeable. A lemonade, each glassful (6 to 8 oz.) of which contains 10 gr. of sodium chloride and 5 gr. of potassium carbonate, with a teaspoonful of lemon juice, is given every two hours to adults. The suggestion, he claimed, is based upon so much of reasonableness and simplicity that it is to be recommended that physicians should give this measure a fair trial.

The discussion was participated in by Drs. A. H. Smith, W. H. Thomson, Beverly Robinson and G. B. Fowler.

THE SIGNIFICANCE IN PNEUMONIA OF THE ANATOMICAL CHARACTERISTICS OF THE LUNGS.

DR. A. H. SMITH said that in pneumonia the proportion of toxin in the exudate increases until the latter becomes unfitted to act longer as a culture medium, when the further growth of the parasite in that immediate locality will cease. Meanwhile the presence of the exudate, aided by the coagulating effect of the toxin, will have brought about arrest of circulation in the capillaries derived from the pulmonary artery, and the function of the part will be completely suspended. So long as fresh areas of lung are being invaded, so long will the systemic disturbance continue; but when the formation of toxin in the zone last invaded has ceased, there will be a cessation of the general toxic phenomena and a fall of temperature, marking the crisis. The local conditions in developed pneumonia are such that gangrene would be inevitable were it not that the nutrition of the lung is maintained by a circulation distinct from that by which the function is carried on. While the capillaries derived from the pulmonary arteries are completely occluded for many days in the affected part, the bronchial arteries are scarcely implicated, and the nutrition remains intact. In pneumonia, Dr. Smith said, the significance of this double circulation was overlooked until he drew attention to it in the early nineties, and even now is very generally ignored. So, too, the difference between the columnar epithelium of the tubes and the pavement epithelium of the air cells, in relation to the growth of the pneumococcus, is a factor of transcendent importance in the concept of pneumonia, since this makes it clear how it is possible to have pneumonia ever present potentially, and yet continue to escape it actually. As to what constitutes pneumonia, he would contend that a single pneumococcus lodged in an air cell, and causing there its specific irritation and consequent exudation, presents all the essentials of the disease. It matters not, he said, if ten minutes later the organism is swept away by the exudate; the patient will have had a pneumonia, if only a monococcal one. Or if later the bronchiole terminating in the lobule first invaded becomes blocked, and the further spread of the infection is prevented, the patient may escape with a unilobular pneumonia; but he will have had a pneumonia all the same. Indeed, there is reason to suspect that such abortive attacks are very common. What, then, he asked, becomes of the notion that the disease is at first general, becoming localized afterward?

HIGH MORTALITY IN HOSPITAL CASES.

DR. W. H. THOMSON read a short paper on the "Pathology of Chill," the concluding paragraph of which was as follows: "Our bacterial enemies, therefore, are always ready to find some injured place in us, and the damage of a small internal locality caused by the reflex action of the vasomotor irritant, cold, on the surface is undoubtedly often the first step in a serious infection from such a foe as the pneumococcus, which may have been waiting for weeks or months in the mouth, unable to do any mischief until an entrance was made for it by 'catching cold.'" He then went on to speak of the greater mortality from pneumonia in hospital patients as compared with those in private practice. The carrying of a patient in the active stage of the disease, perhaps one or two miles through the streets, to the hospital was itself a source of the gravest danger. Absolute rest in the recumbent posture was an essential in the successful management of pneu-

monia, and he always forbade his house staff to raise a patient for the purpose of examining the chest. In bad epidemics it was not uncommon for patients to die within two hours after admission. In the fatality of pneumonia, as of cerebrospinal meningitis and other diseases, the stage of the epidemic at which the case occurred was an important factor. A fatal result, he had observed, was much less likely to occur when the epidemic was declining than when on the increase or at its height. Fifty years ago he was a student at Glasgow when Hughes Bennett was condemning venesection. He remembered that he lost only one out of twenty-three pneumonia patients, and they were treated with potassium acetate and sweet spirit of nitre. His own opinion was that our present treatment of pneumonia was not as successful in its results as that of fifty years ago. Whatever else we might be doing, it was very evident that we were not giving the antidote to the disease. The true antidote had yet to be discovered.

THE VALUE OF ALCOHOL AND CREOSOTE.

DR. BEVERLEY ROBINSON did not think hospital statistics were of great value. The most useful knowledge and experience, he said, could be obtained in private practice. It was difficult for the hospital physician to individualize his cases, and patients were often in an almost hopeless condition when admitted. As to the matter of stimulants, he believed that nothing was half as valuable as good old brandy. Under certain conditions it was the very best remedy that could be employed. If alcohol were used at all, the preparation should be of the best quality. In any case where an attack of pneumonia was threatened it was his practice to start a croup kettle, using in the solution employed for evaporation a certain proportion of the best beechwood creosote. He knew of no remedy which could approximate it in value when given thus by inhalation. He certainly would not regard it as a specific, but he believed that it was sometimes a great help, just as alcohol was, or as digitalis was. As to the remedy or remedies to be employed, everything depended upon the conditions existing in the particular case.

THE USE OF MINUTE DOSES OF MORPHINE.

DR. G. B. FOWLER said that in ordinary cases he used practically no medication, his aim being simply to make the patient as comfortable as possible. When there was pain or restlessness he considered very small doses of morphine of special value, giving 1-40 gr. as often as necessary. In cases where the conditions demanded their use, he gave alcohol, strychnine and sometimes digitalis. There was no specific in this disease, and in his treatment he simply carried out those measures which his own experience had shown him to be the most satisfactory.

DR. ANDERS said that degenerations of the heart and kidneys were often observed at the post-mortems of pneumonia cases. At such autopsies at the Philadelphia Hospital he had found that there was a large percentage of interstitial nephritis. As to the importance of absolute rest, he believed there was no other disease in which this was so essential to the welfare of the patient, and he did not allow his own patients even to turn in bed without the assistance of an attendant. Pneumonia was a toxemia, and we should deal with it like other toxemias. Elimination should always be aimed at, through the kidneys, the bowels and the skin. The kidneys were the great eliminating channels, and water, given freely in the intervals between the times of feeding, was a useful diuretic. He was also in the habit of employing tepid sponging, not for the purpose

of reducing temperature, but to promote elimination through the skin. In sthenic cases, particularly in country patients, he would urge the advisability of venesection, followed by saline infusion. These measures were likewise of service in cases attended with edema and in several instances of this kind he had been much gratified with the success attending them.

Recent Literature.

The Practitioner's Visiting List, 1906. Philadelphia and New York: Lea Brothers & Co.

This takes the place of the old Medical News Visiting List. The name is changed, but the list presents the familiar and useful features of its predecessor with the moderate revision required to bring it up to date.

The Physician's Visiting List for 1906. Philadelphia: P. Blakiston's Son & Co.

The Medical Record Visiting List or Physician's Diary for 1906. New York: William Wood & Co.

Blakiston's Physician's Visiting List for 1906 marks the fifty-fifth year of its publication. The general character of the booklet is essentially unchanged. It contains the usual facts of interest and undoubtedly will continue to fill the place it has made for itself.

A certain revision of the Medical Record Visiting List had been made in that the lists of remedies and their maximum doses have been altered to meet the changes which have been made, and such as are official in the United States are indicated. Information useful in emergencies has been increased, and other matter usually found in a physician's library has been eliminated. A useful obstetrical calendar is inserted at the beginning of the book.

Both are bound in flexible leather and are of convenient pocket size.

The Microtome's Vade-Mecum. A Handbook of the Methods of Microscopic Anatomy. By ARTHUR BOLLES LEE. Sixth edition. pp. 358. Philadelphia: P. Blakiston's Son & Co. 1905.

Six editions of this widely used book on microscopic methods have appeared since 1885. The author has succeeded in this last edition in maintaining essentially the number of pages of the preceding edition. This has been accomplished by a rigid condensation of the text and certain rearrangements. The nervous system has received particular attention in the new edition, and neurofibril and neuroglia methods are given due attention. Mallory is not given credit for being essentially the co-discoverer of the elaborate Weigert method of staining neuroglia although his work is mentioned in connection with the description of the Weigert method. The book is excellently arranged and remains one of the valuable works on technique. The experience which the author has had through the preparation of six editions naturally has assisted in the elimination of unnecessary details.

Neurotic Disorders of Childhood: Including a Study of Auto- and Intestinal Intoxications. Chronic Anemia, Fever, Eclampsia, Epilepsy, Migraine, Chorea, Hysteria, Asthma, etc. By B. K. RACHFORD, M.D. Svo. pp. 440. New York: E. B. Treat & Co. 1905.

Some of the earlier chapters of this volume appeared a year or two ago in the *Archives of Pediatrics*, and form the nucleus and most of the first part of the present book. The scope of the work differs from that of the ordinary treatise on nervous diseases in childhood. It makes no claim to be a treatise of that sort, but instead it deals with certain of the neuroses as well as with certain syndromes of a neurotic character, or with a neurotic basis, such as recurrent vomiting, recurrent coryza, asthma, fever, nystagmus, pica and the like, which are usually neglected in the ordinary treatises. The so-called organic diseases of the nervous system are not considered. Especial stress is laid upon the importance of toxic conditions in the genesis of many of these disorders. The author's study of the kinship of recurrent vomiting, recurrent coryza, toxic epilepsy and migraine is of especial interest. The chapters on the more familiar neuroses, such as epilepsy and hysteria are practical and clear, but betray a lack of familiarity with the affections from the neurological standpoint. The book is of decided value as a practical treatise, dealing with various affections and syndromes, for a consideration of some of which the student would search the more systematic textbooks in vain.

Anatomy. Descriptive and Surgical. By HENRY GRAY, F.R.S. Edited by T. PICKERING PICK, F.R.C.S., and ROBERT HOWDEN, M.A., M.B., C.M. New American edition, thoroughly revised and re-edited with additions by JOHN CHALMERS DaCOSTA, M.D. Illustrated. Philadelphia and New York: Lea Brothers & Co. 1905.

It is a work of supererogation to review at length a book which has won such a place for itself as Gray's Anatomy. The present volume represents a new American edition from the fifteenth English edition with the revision of Dr. J. Chalmers DaCosta. The subject of descriptive anatomy changes far less than many other branches of medicine from year to year. Improvements are, however, continually being made in presentation, and particularly in the illustration of anatomical facts. This edition provides about five hundred new illustrations, a remarkable showing in view of the fact that the entire volume contains hardly more than twice this number. Many of the other standard textbooks of anatomy have been utilized in finally preparing this edition for the press. An innovation is the use of the new or international nomenclature in parentheses following the currently used terms. This plan is a good one inasmuch as it not only avoids a high degree of confusion, but also tends to introduce in a rational fashion the newer terms. Two articles have been taken out of this edition, namely, those on his-

tology and embryology. This is significant of the progress of specialism, but is, we think, regrettable. However superficial such chapters may be, it is desirable that the student studying anatomy should never fail to realize that histology and embryology are integral parts of the subject. Résumés, however, of important embryological or histological matters have been retained. The book remains the same in general appearance and size as heretofore.

A Manual of Clinical Chemistry, Microscopy and Bacteriology. By DR. M. KLOPSLOCK and DR. A. KOWARSKY of Berlin. Translated by THEW WRIGHT, M.D. New York: Rebman Company. 1905.

This book is the result of the authors' desire to place before their students in convenient and concise form the best methods for daily use in clinical chemistry, microscopy and bacteriology. The editor's translation deserves to find the same favor that the original work has received in Germany. The book contains a large amount of information in a surprisingly small compass. We have examined it with care and commend it highly to practitioners and students. Nearly all the most approved methods in laboratory diagnosis will be found in it, and some of the sections are distinctly better than those in most of the standard works on laboratory diagnosis. The chapter on the examination of the feces is one of the best guides to the clinical study of the subject in English. Other admirable sections are those on the sputum, gastric contents and urine. The poorest portion of the work is that devoted to the consideration of the blood. The authors, however, realize the value of Sahli's hemoglobinometer and the untrustworthiness of the Talquist method. The importance of chemistry in laboratory diagnosis is recognized throughout the volume and the chemical aspects are well presented.

Baby Incubators. A Clinical Study of Premature Infants with Especial Reference to Incubator Institutions Conducted for Show Purposes. By JOHN ZAHORSKY, A.B., M.D., Clinical Professor of Pediatrics, Medical Department, Washington University, St. Louis, Mo. Illustrated, 136 pages. St. Louis, Mo.: The Courier of Medicine Company. 1905.

In this little book Dr. Zahorsky gives his experiences in the care of the babies in the Incubator Building at the Louisiana Purchase Exposition at St. Louis. He not only describes the incubators and the care of the babies, but also draws many valuable conclusions both from their defects and their advantages. He also made a careful study of the caloric needs, temperature, nutrition and infections in these babies and gives his results in detail. The book is well worth study and cannot fail to be of much interest to those who have to deal with premature infants.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JANUARY 11, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico. \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 BROMFIELD STREET, BOSTON, MASS.

REPORT OF THE MASSACHUSETTS HOSPITAL FOR EPILEPTICS.

THE progress in the care and treatment of epileptics is reflected each year in the annual reports. The time is rapidly approaching when the work done, and tabulated in these reports, will form a mass of data from which valuable and far-reaching deductions may be drawn. We have before us the report of the Massachusetts Hospital for Epileptics for the official year ending Sept. 30, 1905. The trustees' statement, written by Dr. William N. Ballard, Chairman of the Board, makes mention of the increase in the number of patients and the facilities for their care. An additional assistant physician has been appointed, which makes four in addition to the superintendent who has general charge of the medical work. On Sept. 30, 1904, the institution accommodated 459 patients. One year later there were 521 patients, which unfortunately has led to the necessity of providing floor beds, particularly in the male wards. It is, however, expected that this overcrowding will be relieved by the opening of a new building for men in the spring. As we have repeatedly had occasion to remark, while unfortunate from the point of view of hospital management, overcrowding is the natural consequence of the success of an institution, and must be continually met by increased accommodations. The erection of a new building for men has been rendered possible by the appropriation of \$80,000. In design the building is to be made up of many single rooms for the accommodation of noisy and troublesome patients. This building, however, will not be sufficient to meet the full demands of the situation,

and the Board of Trustees has decided to ask for a similar sum for the erection of a building for women. The hospital at present provides a three years' training course for nurses, and male attendants are also allowed a certificate for work accomplished. The report of Dr. Everett Flood brings out both what the hospital is accomplishing and also its needs for the future, if its usefulness is to increase. One of the most difficult problems facing the management is in keeping the patients cheerful and suitably employed. Discontent is, however, not a conspicuous feature, and when it does occur is rather the result of early training than of dissatisfaction with the surroundings. We are glad to note that medical work is being systematized and the results disseminated. The custom of staff consultations and daily clinics, which have proved so successful and stimulating in many of our insane hospitals, has been adopted. A statement of the articles written, the autopsies performed, and other branches of the medical work, is given in tabular form. It is unnecessary to again call attention to the need of a generous support for this institution, which, in the comparatively short period of its existence, has become firmly established as one of the best equipped and managed hospitals for this type of patients in this country.

A DAY OF REST FOR PHYSICIANS.

ACCORDING to a cable despatch to the New York Sun, an interesting experiment is about to be adopted in Frankfurt by means of which physicians may have one day of rest in seven. Attention is called to the fact that since the general closing of shops and offices on Sunday went into effect some fifteen years ago, definite advantages have resulted to the people at large. Those classes which do not come strictly under the law of Sunday closing, such as pharmacists, have recently planned by mutual agreement for a partial closing of their places of business on Sunday. The movement has apparently met with the approbation of physicians, and the matter has recently been discussed at a meeting of the Frankfurt Medical Society. It was pointed out that general practitioners are rarely able to leave their professional work even for a day, and it was suggested that the city be mapped out into districts and that the doctors could then arrange with one another in such a way that a definite force might be left at home on Sunday, while the others go into the country care-free. One specialist also for every department of medicine

was to remain at home serving for the whole town. The proposition as finally decided upon is said to have received the unanimous approval of the physicians, and it is proposed to adopt the scheme Jan. 14.

It will be generally recognized that practising physicians, of all classes in the community, have the least free time. Any plan which will permit a change in this regard is certainly to be looked upon with favor, however difficult it may be of accomplishment. We are, however, inclined to think that the plan, as outlined above, will hardly succeed in practice so well as on paper. The public, unfortunately, is to be considered, and we take it that the seriously ill would be unwilling even for a day to part with the ministrations of their own physicians. Nor is it likely that the physicians themselves, under such circumstances, would willingly leave their patients to the care of another, however competent he might be. Finally, even could all such matters be satisfactorily arranged, we question whether a holiday under these circumstances could bring with it the full measure of recreation and enjoyment for which it was designed. A simpler method of recreation for the medical man, and one which is apparently being increasingly adopted, is to leave professional work for a week or a month at a time at such seasons as may be most available. One day in seven is far more difficult of accomplishment, at least in this country, than one month in twelve, although naturally there may be exceptions to this general rule. No doubt, however, conditions are somewhat different in Germany, where methods of enjoyment are simpler and recreation not so laborious an undertaking as here. In any case, we wish the Frankfort physicians success in their somewhat unique plan.

THE HENRY JACKSON FUND.

THE Hon. Robert Bacon, formerly a partner in the firm of Messrs. J. P. Morgan & Co., and one who had already rendered valuable assistance in raising money for the new buildings of the Harvard Medical School, has recently presented to the corporation of Harvard University the sum of \$85,000. The gift was accompanied by the following letter stating the purpose of the donor:

TO THE PRESIDENT AND FELLOWS OF HARVARD COLLEGE.

Gentlemen: It is my wish in adding to the funds now being raised for the benefit of the Harvard Medical School to express not only my interest in this object,

but also, and especially, my affection and esteem for my classmate and friend, Dr. Henry Jackson of Boston, now one of its teachers.

It would give me great satisfaction to realize that this gift should serve to promote those objects in which he is directly interested and could permanently identify his name with the future of the Medical School. Knowing his interest in medical research and the advancement of medical science, and also the eminent services of his father, the late Dr. J. B. S. Jackson, to this school, especially in connection with the Anatomical Museum, it is my desire to increase my original subscription of \$25,000 to the sum of \$85,000—to be known as the Henry Jackson Endowment Fund. The income of this is to be used for providing a suitable annual salary for the Curator of said Museum, and for maintaining its efficiency, as an aid to medical and surgical education and research in such manner as shall be recommended from time to time by the Faculty of the Harvard Medical School.

Very truly yours,

ROBERT BACON.

In accepting this gift the Corporation voted: "That Mr. Bacon's generous and welcome gift be gratefully accepted on the terms stated in the foregoing letter.

"Voted, that the name of John Barnard Swett Jackson, curator of the Warren Anatomical Museum from 1847 to 1879, and its first curator, be given to the curatorship."

There is but one other instance in the list of benefactions to the University, in which a gift has been made in the name of a living teacher. That it has been most worthily bestowed in the present case will be the general verdict of the profession. The addition of the name of the late Dr. J. B. S. Jackson to the title of the curatorship of the Museum is a fitting recognition of his lifelong devotion and able services to the school, both as Professor of Morbid Anatomy and Curator of the Museum.

The new building which will contain the Museum is nearly completed and the collection, which is now one of the best in the country and is being more and more freely used, both for purposes of instruction and original investigation, will find a new home well suited for its future work.

A gift of this sort is peculiarly acceptable, not only to those connected with the Harvard Medical School, who will immediately benefit by it, but also to the larger circle of the profession for whom a great medical institution should stand as a source of the widest information. The expense of maintaining and increasing the resources of a museum of this character is naturally very

great and increases with the richness and variety of its collections. Mr. Bacon's liberal bequest will do much toward setting aside any anxiety on this score, and will unquestionably be far-reaching in its benefits to the entire medical profession.

THE PHILIPPINE JOURNAL OF SCIENCE.

The work which has been done in the Philippines, both in medicine and other departments of research, is hereafter to be represented by a special journal to be known as the *Philippine Journal of Science*. By recent act of the United States Philippine Commission the Bureau of Government Laboratories will be so far expanded that it will hereafter include the former Mining Bureau of the Philippine Government and the united institutions will be known as the Bureau of Science. Heretofore a publication has appeared under the title "Bulletins of the Bureau of Government Laboratories." The new journal is to succeed these bulletins. It will receive articles from persons connected with the government and also from any individuals who may have worthy work to present. In addition to matters relating strictly to medicine, researches on various biological subjects, on chemistry, and on mineralogy, geology and paleontology are to be published. It will at once be seen that a journal of this scope must appeal to a large circle of scientific readers, and will, no doubt, prove an accurate epitome of the large amount of scientific work which is now being assiduously done throughout the islands. The journal will be issued as material accumulates, but it is expected that it will appear approximately once a month.

It is certainly to the credit of American energy that a laboratory system has within the few years of American occupation been firmly established in the Philippine Islands. The difficulties to be overcome in the way of general apathy on the part of the people, the trying character of the climate and the inherent difficulty of the problems under consideration, render the progress which has been made most noteworthy. The further concentration of the general laboratory scheme which this journal foreshadows is unquestionably in the line of progress and certainly is to be regarded as one of the most creditable events connected with the American occupation.

MEDICAL NOTES.

OFFICERS OF THE NEW YORK NEUROLOGICAL SOCIETY. — At the annual meeting held on Jan. 2, 1906, the following officers were elected for

the ensuing year: President, Dr. Joseph Fraenkel; first vice-president, Dr. Adolf Meyer; second vice-president, Dr. J. Ramsay Hunt; recording secretary, Dr. Edwin G. Zabriskie; corresponding secretary, Dr. F. K. Hallock; treasurer, Dr. G. M. Hammond; councillors, Drs. M. Allen Starr, Charles L. Dana, Joseph Collins, J. Arthur Booth and William M. Leszynsky.

THE HARVEY SOCIETY. — The fifth lecture in the Harvey Society course will be given by Prof. W. H. Park at the New York Academy of Medicine on Saturday, Jan. 20, at 8.30 p.m., on the subject, "A Critical Study of Serum Therapy." All interested are invited to attend.

THE AMERICAN JOURNAL OF UROLOGY. — A new journal, to be known as the *American Journal of Urology*, is announced under the editorship of Dr. Charles Greene Cumston of Boston, and published under the auspices of the American Urological Association. As its name implies, the journal, which is to appear monthly, will be devoted to the pathology and treatment of the medical and surgical diseases of the genito-urinary system. The journal as it now appears in its second volume is so far changed in form as well as in management that it is practically a new publication.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Jan. 10, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 43, scarlatina 32, typhoid fever 11, measles 153, tuberculosis 43, smallpox 0.

The death-rate of the reported deaths for the week ending Jan. 10, 1906, was 18.19.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Jan. 6, 1906, was 234, against 220 the corresponding week of last year, showing a increase of 14 deaths and making the death-rate for the week 20.50. Of this number 122 were males and 112 were females, 231 were white and 3 colored; 125 were born in the United States, 103 in foreign countries and 6 unknown; 18 were of American parentage, 150 of foreign parentage and 30 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 38 cases and 2 deaths; scarlatina, 30 cases and 10 deaths; typhoid fever, 11 cases and 2 deaths; measles, 171 cases and 4 deaths; tuberculosis, 40 cases and 22 deaths; smallpox, no cases and no

deaths. The deaths from pneumonia were 40, whooping cough 4, heart disease 25, bronchitis 10 and marasmus 3. There were 8 deaths from violent causes. The number of children who died under one year was 42; the number under five years, 59. The number of persons who died over sixty years of age was 62. The deaths in public institutions were 74.

ATTENDANCE AT THE BOSTON TUBERCULOSIS EXHIBITION.—The attendance during the Boston tuberculosis exhibition, which ended Jan. 7, was 24,560. This is a larger number by 6,960 than attended the New York exhibition held a few weeks previously. This is an excellent showing, and no doubt demonstrates the value of wide publicity in a matter of this sort.

PRESIDENT ELIOT ON FOOTBALL.—The report of the President of Harvard College, now in print, but not yet published, is said to contain the most emphatic arraignment of the present game of football which has so far appeared; and in some statements it has not been gently dealt with.

APPOINTMENT OF DR. F. B. LUND.—As one of the latest official acts of Governor Douglas, Dr. Fred B. Lund of Boston has been appointed one of the Board of Trustees of the Medfield Insane Hospital in place of Mr. John G. Park who has recently died. It is eminently fitting that the medical profession should be represented on the boards of trustees of our public institutions.

BOSTON TUBERCULOSIS HOSPITAL.—Dr. Frederick I. Knight has recently expressed his opinion regarding the needs for the treatment of tuberculosis in Boston by urging the necessity for a hospital in the neighborhood of the city where advanced and for the most part hopeless cases may be cared for. For this type of case he thinks a well-built house or houses should be provided, and that such patients should by no means be exposed to the rigorous treatment to which incipient cases are now subjected. Provision for the incipient cases is made at Rutland and elsewhere, and is not so crying a need as a hospital for those in the more advanced stages of the disease. For those cases which are too advanced for Rutland, and yet have not reached the hopeless stage, shacks and buildings of cheaper construction might be erected.

NEW YORK.

BEQUEST TO ST. LUKE'S HOSPITAL.—By the will of the late Alice Hamilton the sum of \$3,000 is left to St. Luke's Hospital.

OFFICERS OF MEDICAL ASSOCIATION OF GREATER CITY OF NEW YORK.—At the annual meeting of the Medical Association of the Greater City of New York, which was held at the Academy of Medicine on Jan. 8, Dr. T. E. Satterthwaite was re-elected president, Dr. R. E. Van Gieson, vice-president; Dr. P. Brynberg Porter, recording secretary; Dr. J. Blake White, chairman for the Borough of Manhattan, and Dr. R. W. Wilcox, member of the Executive Council.

VITAL STATISTICS FOR 1905.—The vital statistics for the year 1905 are of a very satisfactory character. The total number of deaths in the city was 73,540, as against 78,060 in 1904; the death-rate being 18.25 per thousand of the estimated population, as against 20.10 in 1904. It is stated that this death-rate is the lowest but one ever recorded by the Bureau of Vital Statistics, while, notwithstanding the serious epidemic of cerebrospinal meningitis during the earlier portion of the year, the contagious disease rate is the lowest on record. The number of births reported was 103,852, as against 99,555 in 1904.

HEREDITY AND ENVIRONMENT.—After giving the subject three years of careful study, E. Fellows Jenkins, chief probation officer of the Children's Court, which was established in 1903, is convinced that environment is a far greater influence than heredity in determining a child's career. In the course of his report for 1905 this official says: "Perhaps the best proof of the contention that environment has the strongest influence on the development of character is found in the records of the New York Society for the Prevention of Cruelty to Children, which, during thirty years has investigated cases involving the social and moral welfare of over half a million children."

REPORT OF HEALTH DEPARTMENT.—The weekly reports of the Health Department show that during the month of December the mortality in the city represented an annual death-rate of 17.33, as against 16.42 in November and 18.77 in December, 1905. The corrected death-rate, excluding non-residents and infants under one week old, was 16.31. Among the few causes of death which showed a diminished fatality were Bright's disease and nephritis, the weekly average of deaths from which decreased from 121 in November to 117½ in December, scarlet fever, in which the weekly average decreased from 6.5 to 5.5 and pulmonary tuberculosis, in which the weekly average decreased from 167.5 to 164.5. Among the diseases which showed an increased

mortality were the following: The weekly average of deaths from whooping-cough increased from 3 to 4; from diphtheria and croup, from 26 to 36.75; from epidemic cerebrospinal meningitis, from 10 to 15.75; from acute bronchitis, from 27.75 to 31; from pneumonia, from 139 to 151.4; from bronchopneumonia, from 72.75 to 85.25; and from organic heart diseases, from 101.5 to 105.25. It is noticeable that while the death-rate from diarrheal diseases was about the same as in November, the number of deaths per week in the last fortnight of December was nearly double the mortality from this cause earlier in the month. This result, it would seem highly probable, was due to the improper and over-feeding of young children during the Christmas season.

APPROPRIATIONS.—At the last meeting of the year of the Board of Estimate and Apportionment, appropriations to the amount of \$291,000 were made for Bellevue and Allied Hospitals; \$244,000 to be used for the new additions and to purchase other hospital property, and \$50,000 for present needs. The Board also appropriated \$305,000 for the purchase of seven sites for children's playgrounds in the Borough of Brooklyn. The Controller of the State of New York reports that during the past year \$3,700,000 was paid for the care and treatment of the insane, and \$2,100,000 for charitable institutions other than the state hospitals. The total cost of maintenance of the sixteen charitable institutions under the jurisdiction of the Fiscal Supervisor exclusive of the state hospital for incipient pulmonary tuberculosis at Ray Brook, was \$1,438,161, as against \$1,431,984 in 1901.

Obituary.

PROFESSOR ALFRED SCHAPER.

PROF. ALFRED SCHAPER, whose death occurred a few months ago, is well remembered in this community by many friends and former pupils. He came to Boston in 1895 to take the position of Instructor of Histology and Embryology in the Harvard Medical School and began his work as a teacher in October of that year. For five years he remained connected with the school, and was promoted to the position of Assistant Professor of Histology and Embryology in 1899.

Professor Schaper was born May 25, 1863, in Braunschweig. His father held the position of Chief Marshal of the Grand Ducal Court and bore the title of Hofrath. After completing his studies at the gymnasium young Schaper went to the University of Greifswald, where he remained for two years, and then went to Munich for three years, taking his degree at the state

examination in January, 1889. He had first thought of entering into practice, but that was entirely against his natural bent, and he soon turned to purely scientific work, having many of the natural gifts of the born naturalist, a fondness for out of doors, eagerness in seeking intimacy with living nature, an unceasing appetite for information, and a natural endowment for all forms of laboratory work. He had profited thoroughly by his university training, and became a master of embryological research, making his observations with care, not resting satisfied until they were really complete, and then applying them to establish conclusions of wider interest. His numerous published investigations testify alike to his industry and his ability. As a teacher, also, he won distinguished success, getting the confidence of the students and securing their esteem by his evident mastery of the subjects which he taught. He contributed in liberal measure to the development of scientific work at the Harvard Medical School, and exerted, while he was in this country, a very beneficial influence, especially upon the younger men connected with the school, and his retirement from our service was sincerely regretted by his many friends, who had learned to value and appreciate his gentle, modest and lovable character.

Upon leaving Boston he returned to Germany and received a call as Professor Extraordinary to the University of Breslau, taking the place of the late Professor Born, and, at the same time, Schaper was made the head of the Embryological Division of the Anatomical Institute, and First Professor under Professor Hasse.

Schaper's investigations were nearly all in the embryological field, where he had a secure mastery and appreciation of the general problems of vertebrate morphology. A number of his most important publications concern the structure and histogenesis of the nervous system. They all show that he was a conscientious and competent workman. While in America he edited an American edition of Stöhr's textbook on histology. This work was far superior to anything at that time available in the English language, and the publication went rapidly through several editions, being widely used throughout the country, and certainly contributed a great deal to the elevation of histology teaching in all our medical schools. At the time of his death Professor Schaper was working upon a new textbook of histology, the plan for which was formed before he left America, and which was to have as its special distinctive quality the presentation of the whole subject from the development point of view. This work, had it been completed, would, I think, have proved a real and inspiring innovation in histological science.

Professor Schaper married in 1896 an American lady, Miss Mary McPherson, whose acquaintance he had made in Zurich. She survives him.

Professor Schaper was a gifted and enterprising investigator with high aims. His memory will long be cherished by those who knew him in this country.

CHARLES S. MINOT.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, DEC. 30, 1905.

| CITIES. | Population. Census, 1905. | Reported deaths in each. | Deaths under five years. | Percentage of deaths from | | | | | |

Deaths reported, 3,320; under five years of age, 893; principal infectious diseases (smallpox, measles, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption), 758; acute lung diseases 506, consumption 288, scarlet fever 19, whooping cough 13, cerebrospinal meningitis 69, smallpox 0, erysipelas 7, puerperal fever 7, measles 25, typhoid fever 43, diarrheal diseases 102, diphtheria and croup 78.

From whooping cough, New York 5, Chicago 2, Philadelphia 1, Baltimore 2, Fall River 2, Lowell 1. From scarlet fever, New York 6, Chicago 8, Philadelphia 1, Boston 2, Brockton 1, Waltham 1. From cerebrospinal meningitis, New York 63, Philadelphia 1, Boston 2, Worcester, Lowell and Lynn 1 each. From erysipelas, New York 4, Philadelphia 2, Providence 1, Boston 2. From typhoid fever, New York 7, Chicago 14, Philadelphia 14, Baltimore 1, Providence 1, Fall River, Lowell, Springfield and Beverly 1 each, Brockton 2. From measles, New York 12, Chicago 3, Philadelphia 3, Baltimore 1, Boston 4, Worcester 1, Revere 1. From diphtheria and croup, New York 38, Chicago 14, Philadelphia 8, Baltimore 3, Providence 1, Boston 2, New Bedford 3, Springfield 2, Worcester, Lowell, Lawrence, Haverhill, Newton, Everett and Quincy 1 each.

In the seventy-six great towns of England and Wales, with

an estimated population of 15,609,377, for the week ending Dec. 23, 1905, the death-rate was 17.8. Deaths reported 5,321; acute diseases of respiratory organs (London) 252, whooping cough 123, diphtheria 77, measles 124, smallpox 0, scarlet fever 51.

The death-rate ranged from 8.6 in Hastings to 28.8 in Preston; London 19.4, West Ham 12.7, Brighton 9.8, Southampton 18.2, Plymouth 16.2, Bristol 19.1, Birmingham 20.3, Leicester 17.8, Nottingham 13.5, Birkenhead 16.2, Liverpool 21.5, Wigan 19.3, Bolton 13.2, Manchester 21.0, Salford 15.1, Halifax 15.9, Bradford 12.7, Leeds 16.9, Hull 20.2, Sheffield 15.5, Newcastle-on-Tyne 15.0, Cardiff 14.5, Rhondda 14.2, Merthyr Tydfil 19.1, Kings Norton 12.7.

METEOROLOGICAL RECORD.

For the week ending Dec. 30, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

| DATE | Barometer. | Thermometer. | | Relative humidity. | | Direction of wind. | | Velocity of wind. | | Wet'n'r | | Rainfall in inches. | | |

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING JANUARY 6, 1906.

R. A. CAMPBELL, acting assistant surgeon. Appointed acting assistant surgeon from Jan. 9, 1906.

G. G. HART, acting assistant surgeon. Appointed acting assistant surgeon from Jan. 10, 1906.

W. H. BLOCK, acting assistant surgeon. Appointed acting assistant surgeon from Jan. 12, 1906.

C. G. HENDON, medical inspector. Having been examined by a retiring board, and found incapacitated for active service on account of disability incident thereto, is retired from active service, from Dec. 15, 1905, under provision of section 1453, Revised Statutes.

J. F. MURPHY, assistant surgeon. Ordered to the Naval recruiting station, Omaha, Neb., Jan. 24.

C. K. WISS, acting assistant surgeon. Detached from the naval recruiting station, Omaha, Neb., Jan. 24, and ordered to the naval hospital, Washington.

J. T. MILLER, acting assistant surgeon. Appointed acting assistant surgeon from Jan. 9, 1906.

L. O. SCHETRY, pharmacist. Appointed pharmacist Dec. 27, 1905.

SOCIETY NOTICES.

ANNUAL MEETING NEW ENGLAND HOSPITAL MEDICAL SOCIETY.—The annual meeting of the New England Hospital Medical Society will be held at Hotel Nottingham, Thursday, Jan. 18, 1906. Dinner will be served.

There will be a symposium of Medical Study and Travel Abroad, by Drs. Smith, Culbertson, Call, Palmer, Bond, Denig, Myrick, Mee, Haynes, Youngman, Nagle.

BLANCHE A. DENIG, M.D., Secretary.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The annual meeting of the society will be held at the Medical Library building on Monday, Jan. 15, 1906, at 8.15 P.M. Dr. James C. Marshall will read a paper entitled, "John Hunter." The annual business meeting will be held at 7 P.M. A full attendance of the members is desired.

ARTHUR K. STONE, M.D., Secretary.

OPEN-AIR TREATMENT OF BONE TUBERCULOSIS AT THE WELLESLEY CONVALESCENT HOME: WITH A LIST OF THIRTY PERMANENTLY CURED CASES.*

BY B. H. BRADFORD, M.D., BOSTON.

THE efforts of the various societies devoted to controlling tuberculosis have been directed so actively towards combating phthisis pulmonalis, that the success of previous attempts and the present efforts in the treatment of bone and joint tuberculosis are in danger of not receiving the notice which they appear to merit. This is, perhaps, not strange as the individual suffering from consumption is often an active member of society and frequently very much in evidence. The Dame aux Camelias and Mimi, the heroine of the "Vie de Bohème," to say nothing of the hosts of untimely deaths of those of brilliant promise, may be said to have advertised consumption of the lungs, placing it more in evidence than is true of the disease of a fretful and deformed child who is kept as far as possible out of sight. And yet, not only does bone tuberculosis in children present equal demands on the sympathy of the community to those offered by pulmonary phthisis, but the beneficial effects of proper care are even more evident in the treatment of the former than the latter affection.

In our community, efforts for the country-air treatment for bone tuberculosis began many years ago, and, at present, the existing organizations that are attempting to meet the demands of an increasing immigrant pauper class can justly claim the continued and increased support from the charity workers and givers while the results which have already been gained furnish a sufficient guarantee for the quality of the work.

The first systematic attempt to combat what were considered the serofulous affections of the bone in our city, and, perhaps, in our country, was made by the late Miss Anne Robbins, who devoted the best years of her life to the founding, in Boston, and development of the House of the Good Samaritan, in 1865-70, containing a ward which was set apart for the especial care of children with Pott's disease and hip disease, she also later established a country home in the suburbs of Boston. Although this attempt in America was antedated by the work of an humble French woman who began in 1855 to care for, at the sea-shore home at Berck sur Mer, a few of the serofulous children of the city of Paris, and laid the foundation for a most beneficent and extensive institution, yet Miss Robbins is to be regarded as a pioneer in America, and the amount of good which she accomplished is perhaps comparable in meeting the needs of our community of that time with the work in France where an even greater need existed in the larger city of Paris.

Shortly after Miss Robbins had shown the advantage of the especial care of cases of bone tuberculosis, the Boston Children's Hospital was founded, and later a country convalescent home was opened in connection with that hospital, a number of charitable ladies under the leadership of Mrs. Robert C. Winthrop entering zealously into the work. The success of the Children's Hospital and its adjunct convalescent home in the treatment of bone tuberculosis has been greater than is generally known. Nearly ten thousand cases of tuberculosis of the bones and large joints in children have been observed, recorded and carefully treated in these institutions in the last thirty years. The experience gained amply demonstrates the curability of bone and joint tuberculosis as well as that these affections are greatly helped by the fresh air of the country, and that in a large number of cases at a certain stage where every other method has been attempted this treatment may give the stimulus that is most beneficial.

The methods employed in the surgical treatment of tuberculous hip and spine affections need not be described here as they appear in various publications and reports; but attention is directed to the recent improved methods introduced at the Wellesley Convalescent Home for the open-air treatment in bone tuberculosis by the Ladies Aid Association of the Children's Hospital, under the energetic leadership of Mrs. Oliver Peabody.

Taking advantage of the destruction, by fire, of the buildings of the former Convalescent Home three years ago, the managers of the Institution, following the suggestion of Dr. H. L. Barrrell, decided to treat convalescent cases of bone tuberculosis by the open-air treatment in place of what may be termed the country-air treatment formerly and generally employed. At present not only is the Institution arranged for the protection and care of children in a well-arranged country house, but a large number are placed in shacks with free opening to the outer air. Provision is made for only one hundred of these children, but with a comparatively small increase of outlay the Institution is capable of taking care of almost any number of tuberculous cases in children, both of bone and of lungs.

Experience seems to have taught those who have had the direction and care of these cases that in our climate and environment a situation on the interior, if well selected, is, on the whole, more useful during all the months of the year than a sea coast site. The seaside sanatoria in Europe and in our country have proven their usefulness, but it must be remembered that the sea coasts in Europe present a different climate from that which in the winter surrounds our bleak coast. The seaside sanatoria with us in New England are as a rule closed or need to be during the early autumn and winter and are chiefly used during the hot months of the summer. At Wellesley, however, cases are treated with the country treatment with benefit during the whole year, thus furnishing the proper tonic to the children,

*Read at the meeting of the Suffolk District Medical Society, Oct. 28, 1905.

when the severe storms of our coast during the winter period would make confinement in the house desirable, provided the institution had been placed in a more bleak situation.

The results of the open-air treatment furnished to these delicate children has been most gratifying and remarkable, as is shown by the notes and records that were taken by the surgeons in charge of the Convalescent Home, Drs. Dane and Thorndike and Drs. J. Adams and Lamb. The reports prepared by Dr. Adams and Dr. Lamb show that a marked increase in weight and in hemoglobin follow the change from the ward of the hospital to the open-air shacks of the Convalescent Home. The benefit in many instances is much greater than can be indicated by any chart or record, but the simple fact that an average gain of a pound a week followed the transference of a non-selected number of patients from the wards of a well appointed hospital to the open air of the Convalescent Home is something which is worthy of careful consideration. It will be remembered that the children in these instances were not taken directly from the slums or tenement houses, but had for many weeks received the best care and food in a well appointed hospital. They were then taken to the Convalescent Home and given the benefit of an open-air treatment, not simply during a few hours of the day, but both night and day. As most of these cases were chronic affections, the gain cannot be attributed to an arrest of the disease, but may be regarded as due to the fact that in one instance in the hospital ward they are surrounded by air which is not fresher than that which is to be found in the usual well appointed buildings, which is certainly much inferior to that given in tent life or its equivalent.

The experience gained at Wellesley corresponds to that of other observers elsewhere in the treatment of pulmonary tuberculosis, but the investigations at the Wellesley Convalescent Home are even more convincing than many others, for the reason that they are confined to cases of bone and joint tuberculosis, and in most instances to cases who have for some time previously received excellent care in good surroundings.

There remains in the minds of many a belief that even where an apparent cure has been gained, in the treatment of these affections on account of some underlying constitutional vice, the patient remains doomed to a life of disability, poor health or early death.

The following cases will serve to show the error of this opinion and that bone and joint tuberculosis is capable of a definite cure, permanent after the bone has cicatrized. Many of the following cases were treated for a time in hospitals. In the majority, however, the care was entirely at home, and in all the greater part of the treatment was home treatment.

CARIES OF SPINE.

D. Boy of five years, with upper dorsal caries, treated in a recumbent frame for eight months, followed by the application of an antero-posterior support with

head attachment. In the early stages the patient gave evidence of a relatively extensive process with pain, sharp knuckle, disability; two vertebrae were evidently involved. The treatment was continued with care for five years, the brace being worn constantly. The result was a definite cure. At the age of twenty-four the patient is strong and active with no noticeable projection, but showing in the bare back a flattening of the upper dorsal curve and an exaggerated compensatory lordosis. The patient has passed through his undergraduate courses at a leading university and has taken part in athletics and was in good health.

Case of cured hip disease, twelve years after cessation of treatment.

H. A girl of fourteen, with a sharp mid-dorsal knuckle with some acute symptoms. Underwent treatment by plaster jacket and brace treatment for several years which resulted in a permanent cure. At the age of thirty patient was married and has two children and remains in excellent health.

W. A boy of six years, with severe upper dorsal curve, with marked deformity. Treated for ten years in recumbency and brace. Made a permanent recovery with arrest of growth and severe deformity. Graduated from a medical school and became a practitioner of medicine.

P. Girl of five years with severe low dorsal caries, double abscess requiring incision and drainage. Recumbent treatment for two years followed by jacket treatment for four years. At the age of twenty had made an entire recovery and was in excellent health. No resulting deformity, but slight increased lordosis.

B. Boy of the age of five years. Sharp mid-dorsal caries. Patient treated for five years. Ultimate condition reported to be good ten years afterwards.

S. Boy of four; mid-dorsal caries, slight projection. Treated with brace and jacket for four years, with permanent recovery. Patient became an active lawyer and is practicing his profession at the age of twenty-five.

W. Girl of six years. Caries of spine at junction of upper and middle third. Treated for several years with brace and corset with a permanent cure, with slight deformity, but some shortening of figure. Patient became a school teacher and is active at the age of twenty-eight.

T. Age, three years. Cervical caries of acute type with complete paralysis of lower extremities and trunk, treated by recumbent treatment with frame for eight months with disappearance of paralysis, followed by brace treatment with heel support. Complete cure without deformity, enabling the patient to enter Harvard University, taking part in all student activity with no vestige of paralysis or deformity, with the exception of a slight flattening of the trunk between the shoulders.

R. Boy of five. Low dorsal caries with lumbar abscess. Treatment for six months with recumbency, with disappearance of the abscess, followed by jacket treatment for four years. A permanent recovery at the age of eighteen with normal activity and no deformity.

P. Boy of three. Severe low dorsal curve with marked deformity, treated by jacket worn for eight years. Disease of an active type with final arrest and permanent cure, but with marked deformity and some arrest of growth. Patient at the age of twenty-three a student, but with limited activity.

M. Age, two and a half years. A severe caries in the mid-dorsal region with sharp projection, but no deformity. Kept on a recumbent frame for three years on account of marked activity of symptoms, with plaster jacket worn for eight years. Abscess in left groin which became absorbed. A complete recovery without deformity and with great activity at the age of fourteen. No arrest of growth.

P. Woman. Caries of spine in the lower dorsal region treated at the age of eighteen. Treated by Dr. C. F. Taylor with braces, with a definite cure, with but little deformity, though some arrest of growth, and at the age of fifty. At this time were noted symptoms of the appearance of a second focus in the cervical region for which a support was applied with entire relief of symptoms. During this period no reappearance of the symptoms from the old lumbar dorsal caries, and two years later the patient was in good health permitting her usual activity.

M. Practicing physician, thirty years of age. Large healthy man. Six months following a fall from a bicycle was seized with symptoms of pain and disability which eventually caused a bed-ridden condition and the development of a small lumbar abscess, and extreme pain when moved. Slight lumbar vertebral projection. Treated by pocket and bed recumbency for three years, followed in four years by a sufficient recovery to enable him to practice his profession, requiring the use of a stiff corset when moving about. In the early stages of treatment a fistula in ano developed requiring operation, but with ultimate cure. At the final report the patient was enjoying excellent health and able to resume his professional work.

B. Woman, fifty years of age. Painful caries with a sharp kink in low dorsal region requiring plaster jacket with four months of recumbent treatment, followed by two years of plaster jackets, and three years of stiff corsets. Large lumbar abscess which became absorbed. Patient at the age of sixty was in admirable health, with but slight projection and no noticeable deformity, is active, and without support.

H. Girl of five. Severe lumbar caries with suppuration. Treated by plaster jackets and recumbency followed by brace treatment. Treatment continued for ten years. Patient at the age of twenty-four was a healthy, active woman, a teacher of music in the public schools, with no noticeable deformity except a projection of the lumbar spines visible in the bare back. Patient subsequently married.

TUBERCULOUS DISEASE OF HIP.

F. A girl of eight with suppurative disease of the hip joint, requiring four years' treatment. Abscess incised, sinus remained for several years and finally healed. The patient recovered; was married at the age of twenty-eight and was the mother of a healthy child. Slight shortening and some limitation of motion of the hip joint.

L. Girl. When three years old suffered from hip disease requiring treatment for three years; the father in the mean time dying of phthisis. Patient was seen fifteen years afterwards with a complete recovery, complete establishment of motion and no shortening; walks without a limp. Was a pupil in a female college. In admirable health.

B. Male. Taken with acute hip disease at the age of nineteen, requiring treatment for five years. Recumbent for six months; later ambulatory. Brace treatment with a complete recovery; no shortening or deformity, but a limitation of motion at hip joint. Patient at the age of forty-five was leading an active life; enjoying perfect health.

C. At the age of ten was treated for hip disease for five years, with the development of an abscess. Cure was established with a fair motion at the hip joint, but with one inch shortening. Patient grew to healthy womanhood and was married at the age of thirty.

H. Male. Severe hip disease in early childhood, suppurative type and sinus which persisted for twenty years. Ultimate recovery with a useful limb. Complete healing of sinus and but slight deformity. At the age of fifty is engaged in a responsible and active business occupation.

D. Severe hip disease of a painful type at the age of seven, requiring treatment for six years, with persistent sinus for several years. Ultimate recovery with a flexed hip requiring operative correction. At the age of twenty-eight the patient is in admirable health, the father of two healthy children and engaged in an active occupation.

B. Hip disease of an active type in a rapidly growing boy of five years. Treatment necessary for four years with a definite cure, but with deformity. Operative rectification for deformity necessary. Patient at sixteen is in excellent health, but has over-grown his strength.

G. Hip disease of subacute type in a boy of six. Treatment necessary for four years. Complete recovery. At the age of thirty patient is in excellent health with no deformity but some stiffness of hip joint.

D. Suppurative hip disease in child of eight. Treatment for five years. At the age of thirty patient was in excellent health and engaged in an active occupation.

D. Boy of nine. Hip disease of a subacute type. Treatment for four years. Complete recovery with some limitation of motion at hip joint. Patient sufficiently well to serve in the volunteer navy in the Spanish-American War.

G. Boy of six. Severe hip disease requiring treatment for six years with substantial recovery, but with deformity. Defect corrected and at the age of twenty-six in admirable health and engaged in an active occupation. Married.

O. Girl of five, attacked with suppurative hip disease in both hips requiring treatment for ten years. Made an excellent recovery with limited motion at both hips. At the age of twenty-eight married.

W. Male. Afflicted at the age of five with caries of the spine, and subsequently with tuberculous disease of hip joint. Was a sufferer and invalid for fifteen years. Made a sufficient recovery to study a profession, and at the age of thirty is in good health though badly deformed.

B. Boy of six with hip disease of extreme type. Formation of abscess and caries of the head of the femur and pelvis, requiring amputation at the hip joint. Patient recovered. At the age of twenty-eight is married and engaged as secretary in an active business office.

II. Woman. Suppurative hip disease beginning at the age of seventeen, requiring four years' treatment. Recovery of the hip joint and at the age of thirty-five was in excellent health and activity without hip deformity though with stiffness of the hip joint.

The following case of disease of the knee is added:

F. Boy of seven attacked by tuberculosis of the knee joint. Suppurative and severe type, requiring treatment for five years. Patient recovered with a stiff knee, but regained perfect health which enabled him, at the age of twenty-four, to engage in an active occupation.

These cases are of use as showing the condition of patients ten and twenty years after the cessation of treatment. They are without statistical value, but serve as positive evidence of the permanent restoration to health of children stricken with diseases which, without proper treatment, always cripple and frequently kill. The success in such cases should stimulate all efforts in the treatment and control of joint and bone tuberculosis and among them the open-air treatment is by no means the least.

It must be clearly understood that by open-air treatment is not meant that the children pass a few hours in the day out of doors, but that at all times they receive the benefit of air which is not confined in rooms where the entrance and exit of air is limited by fireless chimneys, slightly open windows or air ducts which do not draw. If the condition of the air in almost all sleeping rooms, even in the best appointed houses, or hospital wards is examined at midnight or an early hour in a winter morning, the prevalence of tuberculosis is easily understood, and the hygienic superiority in this regard of the tent life of the savage over the less active life of the civilized, who protects himself from cold by shutting out fresh air is manifest. To Santa Claus in his midnight raids it must be apparent that the best possible Christmas gift to the majority would be a house with a large hole in the roof.

On reading accounts of the sanitary condition of the large cities of antiquity and the Middle Ages when people were crowded in huts littered with unchanged straw, with filth plastering the streets and with no disposal of sewage, the virulence of epidemics which almost depopulated Europe is seen to be explicable. It is not impossible that

in the future the present condition of our cities where the majority of the population spends the greater part of their lives, in the air of rooms polluted with what may be termed atmospheric sewage, will be looked upon with horror by a generation to whom the White Plague will be as unknown as the Black Death or terrible ravages of smallpox are now to us. In the meantime, the open-air treatment of caries of the spine and hip disease not only in southern California or Egypt, but here in New England, even in our rigorous winter, is to be zealously advocated by all who have the health of the community at heart.

WHAT IS THE RELATION BETWEEN HUMAN AND BOVINE TUBERCULOSIS, AND HOW DOES IT AFFECT INMATES OF PUBLIC INSTITUTIONS? *

BY THEOBALD SMITH, M.D.,

Professor of Comparative Pathology, Harvard Medical School.

THE progress made in the past twenty-five years in the study of infectious diseases, notably those of the higher domestic animals, has placed us in a somewhat different position with regard to the question of the intercommunicability of infections between animals and man. When the tubercle bacillus was discovered there was but little known of the definite limitations of micro-organisms to certain hosts. Then pathogenic power towards one to the higher animals meant rather vaguely danger to all others. Now pathogenic power of any microbe towards a given animal species means that and no more, until more has been proved. We may protect ourselves in actual life against possible dangers, but we have not thereby proved that these dangers are real. Unfortunately, much of the anxiety we feel towards infections emanating from the lower animals cannot be placed at rest because the experimental method, the actual test, is inapplicable, and we must content ourselves by roundabout methods, clinical observations, inferences from analogy, and painstaking comparisons between the micro-organisms if they can be seen and cultivated.

To what extent infectious agents are restricted in their activities is shown by the fact that only one of the infectious diseases of man—the bubonic plague—is shared by one of the lower animals, the rat. The plague is known to spread freely from rat to rat, from rat to man, and less freely from man to man, so that some are inclined to the view that the plague is primarily a rat disease. There are other infections which may be transmitted from animals to man, but only under exceptional circumstances. Man does not, as a rule, transmit these to his fellow-man, chiefly because the necessary machinery for transmission is absent.

After the publication of the celebrated work of Koch in 1882, it was generally conceded that bovine and human tuberculosis were absolutely identical, and that ingestion or inhalation of the

* Read at the Tuberculosis Exhibition, Jan. 5, 1906.

baecilli from one source was as dangerous as from the other. Facing this problem of intercommunicability from the standpoint of to-day, the burden of proof really rests upon those who admit such a free transmission from man to animals and the reverse. For we cannot but assume that two bacilli of highly parasitic character, one living in cattle and the other in man, must eventually develop irreconcilable differences stamped upon them by their respective hosts, unless such remarkable mutual affinities exist as those manifested by the plague bacillus. But these should be demonstrated rather than assumed.

It was reasoning of this kind coupled with experimental observations that led me, in 1894, to study more in detail cultures of tubercle bacilli from different hosts. This is a tedious process. It was not until 1898 that a series had been studied sufficiently large to justify the establishment of two races of tubercle bacilli, — a bovine and a human type. This investigation led me to take the position that it was impossible to tell precisely how such differences in the bacilli influenced intercommunicability, and that we must begin to study cases of human tuberculosis to determine more accurately which type of disease may be referred to animal sources.

At the same time I contended that these results contradicted the extreme fear with which bovine tuberculosis was being regarded, and that it did not justify the very heavy expenditure of public funds in the destruction of all tuberculin-reacting animals, and what was still worse, the condemnation by law of the flesh of even the mildest, most insignificant cases as unfit for human food. This position was all the more necessary, since the importance of the strictly human source of tuberculosis, the sputum, was being pushed to the background and our state was appropriating not less than a quarter of a million dollars a year for the eradication of bovine tuberculosis.

Now it is possible that we may be threatened again by legislative schemes to pay out of the public treasury money to defray the immunization of young cattle according to von Behring's scheme. What the state can justly do is to pay for suitable experiments to study this method and to prepare the vaccine, but nothing more. If the state has any money to spare, it should be reserved for the care and housing of human consumptives.

The work of studying the tubercle bacillus along lines laid down by me was being carried on quietly, notably by Ravenel in Philadelphia. It was not, however, until 1901 when the great authority of Robert Koch placed itself directly across the path marked out by sanitarians since the publication of his great discovery in 1882. He maintained not only the radical distinction between bovine and human tuberculosis, but went so far as to regard the bovine disease as a negligible quantity in our struggle against the human disease. While he may be said to have gone too far in this latter position, his views exercised a salutary influence in forcibly drawing

the attention of the world's sanitary machinery from a minor to a major source of disease; and without doubt, the public anti-tuberculosis movement of to-day, of which this meeting is a part, gained an enormous impetus through his somewhat one-sided position.

The wave of opposition raised by Koch's address led to the appointment of a number of commissions to investigate the subject anew. The English government had only a few years before issued a very large report by a Royal Commission, in which the bovine and the human disease were regarded as identical. A new commission was formed at once which established, perhaps, the most elaborate temporary plant in the world for the reinvestigation of this question. A leaflet issued several years ago leads us to infer that in its final report the commission will adhere to the platform of the former commission. A Royal Commission appointed by the Imperial Health Office of Germany has recently issued a series of reports, in which it places itself wholly on the ground taken by me in 1898.

Many minor investigations upon this subject have been made and published during the past four years, which range themselves on one side or the other of this sanitary problem.

If we briefly summarize the results of these investigations, we find two facts firmly established: 1. The conception of two types of mammalian tubercle bacilli, a bovine and a human type. 2. The occasional presence of the bovine type in cases of human tuberculosis.

How often the invasion of the human subject with bovine bacilli takes place cannot be stated with any degree of accuracy, for all investigators have turned their attention chiefly to cases originating in the digestive tract or its associated lymph nodes, *i. e.*, to those cases in which infection through raw milk may have taken place. We are, however, in the position to affirm that the old notion that all tuberculosis originating in the intestinal tract is of bovine origin is not true. Of five such cases studied by me, one was associated with bovine bacilli. Of twelve studied by the German Commission, six were associated with bovine and one with both kinds of bacilli. Ravenel had reported several cases similarly the Department of Agriculture at Washington. I have not at hand the means for calculating the percentage of intestinal tuberculosis associated with bovine bacilli, but it may be roughly estimated at 20% to 40%. This may seem a relatively high rate, but the following circumstance must be taken into consideration:

1. A certain proportion of the cases are stationary. The disease is restricted to the mesenteric lymph glands.
2. Where tubercular ulcer due to thickening of bacilli exist, the bovine origin is often difficult to be admitted when this might be impossible in an intact mucosa.
3. Tuberculosis of a terminal organ is a relatively rare affection.
4. In Japan, where milk does not play any appreciable rôle in the feeding of infant and

children. human tuberculosis, including the intestinal disease, is as common as in other countries.

I can merely refer, in passing, to the question of the transformation of the bovine into the human bacillus in the human body. If this were possible, our efforts to trace the sources of tubercular infection by bacteriological methods would be fruitless. While I am prepared to admit a certain change manifested by reduction in virulence, the evidence we possess is conflicting and hardly in favor of the transformation theory.

It is needless to state that much more work must be done before we can formulate precisely the relation which the bovine bacillus bears to tuberculosis of alimentary origin. In the meantime, certain broad facts stand out above the fog of controversy to which those to whom the health and well-being of large numbers are entrusted may cling with a reasonable amount of confidence.

In the first place, the bovine bacillus has been found almost exclusively in children under ten years of age. Phthisis and the other forms of tuberculosis in adults are, so far as we know, almost wholly of human origin. In institutions in which children are cared for, the source of the milk should receive careful attention, and herds belonging to the institution should be free from any traces of this disease. In institutions harboring adults there need be less anxiety on this point, and if all animals of reduced vitality or whose udders are not above suspicion are eliminated, the danger of infection may be regarded as exceedingly small. This standpoint is based upon the following well-established facts:

1. With few exceptions, cattle reacting to tuberculin are in an early or latent stage of the disease, during which tubercle bacilli are not excreted in the milk.

2. When tuberculosis becomes generalized, which frequently happens after parturition, and the udder and uterus become affected, physical examination and microscopic examination of the secretions should detect it.

To these we may add that it is highly probable that we can successfully resist an occasional tubercle bacillus, and that most of us, at one time or another, have ingested without harm a few bacilli in milk or butter. It is equally probable that our resistance may give way at an unguarded moment when our alimentary tract is being daily flooded with bacilli from a tubercular udder.

In view of these data it is obvious that a careful periodical inspection of dairy herds cannot be dispensed with, and that such inspections should be made a necessary function of state and local boards of health, or of specially organized bureaus, in order that any advanced cases of tuberculosis may be detected, removed and destroyed. More than this cannot be demanded at present in the interest of public health. Yet it should be the pride of the head of every one of our public institutions to keep the dairy herd free from tuberculosis.

SHOULD THE TUBERCULOUS INSANE IN HOSPITALS BE SEGREGATED? *

BY O. F. ROGERS, M.D.,
Trustee of Danvers Insane Hospital.

THE tuberculosis problem presented to the officers of a hospital for the insane is somewhat different from that presented to the medical attendant of the sane.

It is generally not necessary or wise to isolate the tuberculous member of the family, though certain cases in the last stages of the disease constitute an exception to this rule.

If a tuberculous patient and his family are in moderate circumstances, possess ordinary intelligence and are wisely instructed by their physician, the danger of infection is slight, even though very few changes are made in the mode of family life.

But it is otherwise with the insane. Most of the insane are incapable of appreciating the importance of the measures necessary to be taken to prevent the dissemination of the disease, nor can they be trusted to carry out these measures, no matter how simple or how carefully explained to them.

All of the Massachusetts State Hospitals for the Insane are crowded, imperfectly ventilated, and many of the rooms get little sunshine. A large portion of the inmates spend but little time in the open air, especially in the colder months.

Much the larger portion of the insane in hospitals are in a condition of lowered vitality; very many are the subjects of organic changes of a grave character, and a considerable portion are in a condition of mental depression or excitement, very unfavorable to the maintenance of bodily nutrition.

Thus it happens that the inmate of a hospital for the insane lives under conditions favorable to the growth and dissemination of the tubercle bacilli and unfavorable to its destruction, while his capacity of resistance to tuberculosis is greatly reduced by his physical condition.

The result of all these conditions is an enormous death-rate and an even larger proportional death-rate for tuberculosis.

If any proof of this statement is needed, the following figures afford it: During the year 1904 the number of deaths in the city of Boston from tuberculosis was 2.06 per 1,000 inhabitants. During the hospital year, ending Sept. 30, 1905, the number of deaths from tuberculosis in the Danvers Insane Hospital was 17.06 per 1,000 inmates. The institution death-rate for tuberculosis was over eight times the city death-rate. During these same years the city death-rate for all diseases was 17.50 per 1,000 inhabitants; the hospital rate was 116.46 per 1,000 inmates, or about seven times the city rate. The large death-rate is not peculiar to the Danvers Hospital; it is found wherever considerable numbers of the insane are confined within walls.

Very striking evidence of the influence of confinement in causing tuberculosis is afforded by

* Read at the Tuberculosis Exhibition, Jan. 5, 1906.

the statistics of the death-rate of prisons. The yearly death-rate of the State Prison at Charlestown for the period of three years ending in 1904 was 7.31 per 1,000 inmates. Nothing could more clearly demonstrate the excellent physical condition of the prisoners than this death-rate of 7.31 per 1,000 in comparison with the 17.50 rate of Boston and the 116.46 rate of the Danvers Hospital. Yet in spite of the good health of the prisoners and consequent abundant resisting power, tuberculosis caused 38.70% of all deaths in the prison during the ten years ending in 1902. Undoubtedly the cause of this is to be found in the close confinement.

In brief, the situation is this: The hospital must receive all who are committed to it; hence the crowding, with all its results. The mental condition of the patients is such that intelligent and sustained efforts by them to prevent the spread of tuberculosis is not to be expected. The deficient resisting power of the insane due to their physical condition cannot be materially improved. It is self-evident that most of the conditions to which the excessive prevalence of tuberculosis in insane hospitals is due cannot be remedied by any measure now at the command of the trustees.

The trustees and superintendent of the Danvers Hospital, impressed by this fact, have decided that segregation of the tuberculous is the only available remedy. For three years eight or ten female patients were kept in tents on the lawn during the summer months. They enjoyed the tent life and several made rapid improvement. Encouraged by the result of this experiment, the superintendent recommended that two buildings should be erected of capacity sufficient to accommodate all of the tuberculous patients in the hospital. These buildings are now nearly completed. Each building will shelter fifteen patients. They are practically alike, one for women and the other for men. They are about 76 feet long x 21 feet wide. They front the south. Each has a piazza ten feet wide running the whole length of the front of the building. The front is nearly all glass, and there is considerable glass in other portions of the walls. The windows are double, and above each window is a glass transom, and all can be raised or swung. The buildings are heated by steam pipes running beneath the windows on three sides of the wards. Fresh air is taken directly through the walls. A sheet iron arrangement causes the air to flow over the steam pipes before it enters the wards. Each building has two wards, 30 feet x 20 feet, 13 feet high, with a room between them 16 feet x 20 feet containing a fireplace. There is a bath room and a dressing-room that can be kept warm at all times. The walls are lathed and plastered and painted with lead and finished with a coat of enamel. The floor is covered with mild linoleum of the best quality. There are openings for ventilation in the ceilings and gable ends. The wards are lighted by the Cooper-Hewitt electric light. There are no window guards.

There are supposed to be now in the hospital,

about twenty-four cases of tuberculosis. None of this class are excited, or in such condition that they could not be kept, with a reasonable oversight, in the wards as constructed.

It is expected that a day nurse and a night nurse will be able to care for one building. Possibly when full, three nurses will be required. Just what will be the additional cost of caring for patients cannot now be stated, but it is certain that it will not greatly exceed the present cost. Much will depend upon the diet scale adopted. By building these wards the capacity of the hospital is increased by thirty beds, at a per capita cost of about \$125, furnished ready to occupy. The per capita cost of the main hospital, reckoning its capacity as 1,000, is \$1,600. The fact that the state has to provide yearly additional accommodations for four hundred insane, and that the need of economy is urgent, would of itself seem to justify the building of these wards.

The attempt to cure, control, or decidedly diminish tuberculosis by segregation cannot possibly succeed unless the disease is diagnosed early.

If it is true, as I believe it to be, that the average physician does not make an early diagnosis of tuberculosis, it seems that at least one physician in a hospital ought to be given the opportunity to become expert in its detection. Each patient ought to be carefully examined at regular intervals of a few months. This will render possible the removal of the patient from conditions most unfavorable to his recovery to favorable conditions, at a stage when, if ever, favorable results from treatment may be expected, and before he has become a menace to the health of the other inmates of the hospital.

Segregation seems to offer a rational, practicable, and not too expensive remedy for conditions that urgently demand relief.

WHAT SHOULD BE THE STATE POLICY REGARDING TUBERCULOSIS IN INSANE ASYLUMS?

BY OWEN COPE, M.D.,
Executive Officer, Massachusetts State Board of Prisons.

THE insane are entitled to all the resources of medical skill and treatment available in our civilization. If ethical considerations in relation to the tuberculous insane were not superadded on this point, the welfare of inmates, fellow-patients, nurses and others would demand the strictest application of this principle.

The treatment of tuberculosis in the insane presents all the difficulties encountered in dealing with the disease in general and other affections from mental alienation. Its presence can be detected without the most painstaking observation and systematic physical examination, owing to the blunting of sensibility, the morose, indolent and apathetic states, to the advanced degree that cough and other cardinal symptoms

*Read at the Tuberculosis Conference, Jan. 5, 1906.

tions may be so slight as not to attract attention. The insane patient, through weakness of mind, perverse tendencies, delusive ideas or willful misconduct, often cannot be relied upon to co-operate in efforts either to establish the right régime for himself or to safeguard his fellow-patients from danger of infection. Hence, alertness in diagnosis and effective segregation are especially important in the management of this class.

The complete separation of the tuberculous from other insane under felicitous conditions is not easy. Thought must be taken of the different stages of the malady, the character of the patient, his native idiosyncrasies and morbid propensities, his environment as to associates and depressive influences, economy of arrangements for his care and safe custody, the size and location of the institution. The satisfactory isolation of the few tuberculous patients of diverse characteristics in the small hospital involves such difficulties of classification and excessive cost proportionate to the amount of work, as to be almost prohibitive. Such limitations might necessitate their aggregation at some convenient point, possibly in connection with the most suitably situated of such hospitals. Centralization, however, is not desirable in itself. Patients should be kept near their relatives and friends, so far as possible. Small groups of the tuberculous are preferable to large ones. The absolute elimination of the problem from any establishment would be impracticable, owing to the insidious nature of the affection and the obstacles opposing in individual cases, and the attempt might result in inadequate facilities for its treatment. Furthermore, the assemblage of all tuberculous inmates of the hospitals and asylums of Massachusetts would not probably bring together a sufficient number to justify on economic grounds the founding of an independent hospital, while no existing one would be likely to invite such an addition.

The necessity, however, of either contingency is obviated by the suitable location of all our institutions to afford appropriate conditions, and by their adequate size, present or prospective, to facilitate classification and furnish economic warrant for each to deal with the matter for itself.

Naturally, methods will vary at different hospitals, and properly, so far as the essential requirements are met in providing the best conditions of treatment for the patient himself and adequate protection from infection for others. The present tendency seems to be away from the tent, as inconvenient and not habitable during the severe weather of this climate, to the small, inexpensive, one-story, wooden pavilion, habitable all the year round, equipped with the necessary accessories, supplying abundant sunlight and fresh air, one for each sex, in close connection with and administered from the main plant. The Danvers Hospital and Medfield Asylum are about to open such pavilions. Westborough and Taunton are moving in the same direction. Some others are segregating the bed-ridden in special

dormitories; others are using verandas adjoining the wards, where the patients practically live out of doors day and night.

Probably experience will show that a combination of methods will best serve the purpose. Separate cottages are the most desirable form of provision and will best serve the needs of the main body of such patients. Nevertheless, the dangerous or scheming patient will require the safer custody of the closed wards, strictly supervised to prevent violence or escape. The quiet, clean, tractable patient, sensitive to surroundings and associations, will enjoy and receive benefit from the diversions and congenial company to be found only in the better wards in the main building. Spatial separation may be conceded for these advantages, so far as reliance may be placed on the patient's observance of rules necessary for the protection of others, or oversight may be effective to the same end. In such cases, sun-rooms, screened verandas and other adjuncts to the common wards will be indispensable.

WHAT SPECIAL INSTRUCTIONS REGARDING TUBERCULOSIS SHOULD BE GIVEN INSTITUTION NURSES AND OTHER EMPLOYEES?

ARE NURSES CARING FOR CASES OF TUBERCULOSIS IN DANGER OF CONTRACTING THE DISEASE?*

BY JOHN H. NICHOLS, M.D.,
Superintendent State Hospital, Tewksbury, Mass.

It is my purpose to speak regarding tuberculosis in hospital wards, and what is said will have reference more particularly to care and treatment of advanced or terminal cases rather than the earlier stages of the disease.

We have a small proportion of comparatively early cases to care for and believe in the out-of-door treatment for them, and have a camp where these patients can be practically out of doors throughout the year; but, as this stage of the disease and its treatment has been so carefully considered in other parts of the program, I will say nothing further in that direction.

There is no question but what those cases nearing the end of this malady are the ones that appeal most strongly to our sympathies, and, as the considerations, methods and practices for making these patients comfortable are very exacting to the nurse, it seems best that this class of patients should be treated in well-constructed hospital wards, and not in tents, camps or cheaply constructed pavilions. The nurses, and all of those engaged in caring for these patients, need every encouragement and all of the best facilities for caring for the sick that it is possible to obtain.

Our instruction to nurses in caring for consumptives in the hospital wards is practically the same as that which is given to the general public in dealing with the disease. We impress upon them the nature of the infection to which they

* Read at the Tuberculosis Exhibition, Jan. 5, 1906.

are exposed, and teach them about the micro-organism, the tubercle bacillus, without the presence of which the disease — tuberculosis — cannot exist. They are told how vicious and potent an organism it is when it is allowed to have its sway and when things are favorable to its spread, and that it abounds in the forced exhalations and expectoration of consumptive patients, which, when dry, separates into fine particles, mingling with the dust and floating about in the room where it exists, until it is inhaled or taken into the lungs of those occupying the room; then, if the vitality of the person is in a condition favorable to the disease, a tuberculous process is started up in the lungs of the new victim. People in apparently perfect health are liable to contract the disease if exposed continuously to the infection under conditions favorable to its spread, although those in a delicate state of health, or a receptive condition, may be in contact with the disease with but little danger to themselves, provided that all the proper precautions are taken.

The conditions favorable to its spread are filth, foul air, overwork, lack of proper and sufficient food, lack of sufficient exercise and irregular habits. The great enemies of tuberculosis, or safe-guards against it, are cleanliness, fresh air, sunlight, moderate exercise, regular habits of eating, sleeping and bathing, and especially out-of-door life.

We tell the nurses there is great danger in the dust which is in the ward or room of a consumptive patient, which may be laden with the tubercle bacillus, and that all the dust must be kept out of the room, removing it with moist cloths which are rinsed and afterwards allowed to stand in pails containing a solution of some antiseptic or germ-destroying solution.

We advise them not to let the patients breathe in their faces when they are working over them or when talking with them. We teach them that all the sunlight which is possible should be admitted into the room, and that windows should be open at all times of the year, day and night, but, if possible, on the side of the room away from the wind, the patient, of course, being covered with a sufficient number of blankets to keep the body warm.

The expectoration of sputum should be received in paper receptacles made for the purpose, which, with their contents, should be burned every day. It is well also to make use of paper handkerchiefs, or pieces of gauze, which also should be destroyed by burning each day.

In regard to the nurses or other employees contracting the disease while on duty, I believe that nurses in a hospital for tuberculosis, with many patients, in wards that are kept perfectly clean, where dust is always kept down, where the windows are kept open, and where there is no over-crowding of patients, are safer from danger in caring for tuberculous cases than they are in many of the general hospital wards.

I have known times when nurses, especially male nurses, and not infrequently young doctors, objected to a service in consumptive wards, generally, however, because their parents or

others have advised them to keep out of those wards. This advice is unwarranted, for with fourteen years of hospital experience with tuberculosis, during which time we have cared for more than five thousand cases, mostly in the advanced stages of the disease, I have known of only one case where attendant, nurse or physician has beyond doubt contracted the disease in the wards or in the discharge of their duties. I have known of only one death where one of them may have contracted the disease in the discharge of his duties.

For over five years our hospital for consumptives has been situated one half mile from where the nurses go to their meals or their sleeping apartments, and even prior to that time they have always been required to travel out of doors three times a day to their meals and have slept in rooms outside of the hospital buildings, which has, of course, been a condition greatly in our favor, and strongly indicating that a certain amount of out-of-door air is the great safeguard from this disease.

I believe that no competent physician or nurse, conscientious in the work, ought to exhibit any timidity whatever in caring for consumptive patients when they are allowed to control the essential sanitary regulations.

ON THE IMPORTANCE OF EARLY DIAGNOSIS IN CASES OF PULMONARY TUBERCULOSIS.*

BY HENRIETTA C. CLARK, M.D., BOSTON.

Visiting Physician in the Massachusetts State Sanatorium at Rutland, Vt.

There are consumptives and consumptives. Here is our first picture representing the popular idea of a consumptive. He is a thin, cadaverous-looking individual, with sunken-in chest, a stooping figure, hollow cheeks, pallor, hectic flush, high fever, bad cough, feeble walk, short breath and evidences of exhaustion, with hemorrhages, night sweats and many other symptoms, which are only too well known.

Sure enough, that is a fairly true picture of many cases, but nowadays we call these advanced, and they are generally hopeless, and, so far as most of them are concerned, we regret to say, in spite of all that the best medical skill can do, in the best climate in the world, in sanatoria or without, the procession is still marching steadily towards the graveyard, as it always has done.

Here is our second picture. To the casual beholder a consumptive of this class may look almost and sometimes quite like a well man. It is not the symptoms only faintly resemble, suggest those of the first picture, already given. We call these early cases and most of them can be cured. Very often visitors to our State Sanatorium at Rutland, on being shown the cadaverous-looking specimens of men and women, make the remark that they have great difficulty in believing that they can possibly be victims of pulmonary tuberculosis. I am happy to have them today to show you as a sample of the better class of early cases in the State Sanatorium.

* Read at the Tubercular Conference, New York, 1902.

three patients who feel well and who look well externally, but who, nevertheless, have the germs and other evidences of the disease, and might easily be upset by a little improper living. Within a comparatively few years medical science has discovered methods of curing the great majority of cases of pulmonary tuberculosis, if taken before they have progressed far; but to be successful to any considerable extent, the cases must be taken early. Then the cure will not only be more certain, but also far quicker and pleasanter.

If a small fire is discovered in a wooden building, a few dipperfuls or a pailful of water may extinguish it; but if much time is lost, we all know the result. Occasionally a small fire in a wooden building may burn itself out without spreading to the rest of the structure; and undoubtedly now and then a tubercular deposit in the lungs may get well without the institution of rigorous measures, or even without the patient's knowledge that he has had such trouble. Nevertheless, those who are familiar with the circumstances in either case would dread to run the great risk which would come by neglect.

Practically, lung specialists all over the world have proved that fully three fourths of the really early cases can be cured, but exceedingly few of the far advanced cases; and that those in between are more or less doubtful, approaching the status of the class to which they come nearest.

This statement, of great practical import, which is perfectly true and not a bit exaggerated, cannot be made too emphatic. Nor can it be made too often. It should be proclaimed from the house tops, in season and out of season. It should be forced upon the attention of every one in the community. In it are involved some of the most vital questions in the modern crusade against tuberculosis. This crusade cannot possibly succeed, if we neglect the proper consideration of early diagnosis; and unfortunately the victims of the disease are often very unwilling to take it into consideration themselves.

According to our modern ideas, a consumptive is strictly a person who is dying of an advanced tubercular disease of the lungs.

If we could cure all cases of early tuberculosis, we should have no more consumption. An early case of pulmonary tuberculosis bears about the same relation to an advanced case that a tadpole bears to a frog. If we could exterminate the tadpole, we should have no frogs.

In order to exterminate the tadpoles, they must first be recognized. Some men know a frog when they see it, but overlook the tadpole. Many physicians, who can recognize advanced cases of tuberculosis, overlook and fail to recognize the early cases. There is often as much difference between these early and late cases as between the stages of the batrachians.

A few years ago, when almost all cases died anyway, no matter how early they were seen, it did not make much difference at what stage they were discovered. Now that we know that the time element is the most important factor in the

result of treatment, physicians are being especially stimulated to make as early a diagnosis as possible.

SHOULD TUBERCULIN BE USED IN INSTITUTIONS AS A DIAGNOSTIC MEASURE?

Briefly, I should say that occasionally, though not often, it is wise and proper to use it. The first thing to do in all instances is to examine the chest. In the great majority of cases of tuberculosis which come to us, a physician who is skilled in such examination by auscultation and percussion can, by this means, together with the history of the case, properly recognize the disease, and often, too, before the tubercle bacilli (the germs) appear in the sputum. Sometimes, to be sure, the bacilli give the prior information, although they do not show the extent or location of the disease.

But it occasionally happens that the physical examination, the sputum, the symptoms and the history of the case are not sufficiently explicit to clear up a doubt as to the diagnosis, and it becomes desirable to settle it in some other way. In such cases the tuberculin test, which is so much used in cattle, becomes serviceable.

Wide experience has shown that, if properly used, no danger follows its use. It is not infallible and fails in some cases, but in the majority gives trustworthy information. If it reacts, it produces a temporary sickness, lasting for a few days, somewhat like a severe vaccination. For these and other reasons it should not be used in institutions or anywhere else, if we can make a satisfactory diagnosis (as we usually can) in other ways.

THE TREATMENT OF TUBERCULOSIS IN PUBLIC INSTITUTIONS.*

BY WILDER TILESTON, M.D.,
Assistant Visiting Physician, Long Island Hospital.

THE treatment of tuberculosis in public institutions is a broad subject, and the time allotted me is brief, so I shall have to restrict myself to a few general remarks, omitting many details. It may be considered from three points of view, that of diet, of hygiene and of medicinal treatment.

The diet should be nourishing and varied. In food value it should equal, or even exceed, that of a healthy working person, that is to say, about 3,000 calories. This large amount of food is necessary to offset the increased breaking down of the body tissues, which is constantly taking place in phthisis, and to make up for past losses. Care must be taken, however, not to upset the digestion by overfeeding, and the amount of food which can be taken with advantage will vary according to the individual. In order to get in a maximum amount of nourishment, it is best to increase the number of meals to five or six daily. These are to consist of the usual three meals, with additional light meals in the middle of the

* Read at the Tuberculosis Exhibition, Jan. 5, 1906.

morning, in the afternoon and at nine in the evening. For these extra meals a glass of milk and a cracker are sufficient.

For consumptives, food should be as varied as possible, for too great monotony soon takes away the appetite. It should contain an abundance of all three forms of food, — proteids, carbohydrates and fats. An exclusive milk diet is not to be recommended, for it is likely to give rise to digestive disturbances, on account of the large quantities (four to five quarts) which must be taken. Alcohol is better left out of the regular treatment in institutions, for various reasons.

It is of the greatest importance that the food be properly cooked and attractively served, for if it is not, both appetite and digestion will probably suffer. It is well known how much these functions are dependent on the mental state, and it has recently been shown, by experiments on animals, that there may be even entire failure of secretion of the gastric juice, due to psychic influences. I think that the quality of the food in New England institutions is usually good, but it is frequently spoiled in the cooking, and it is here that there is room for improvement.

*Patients with fever usually have some disturbance of digestion and should be fed accordingly. Fever of itself is not an indication to restrict the diet. Gastric and intestinal disturbances call for early and appropriate treatment, for if neglected they may lead to serious impairment of the digestive and absorptive functions.

The weekly weighing of the patient is an important aid to the intelligent treatment of tuberculosis, and is, perhaps, the best guide to the amount of food to be given.

The hygienic treatment of the consumptive next demands consideration. Here the underlying principles are two, — fresh air and rest. Not only should the patient be out of doors all day long, and every day, but, where practicable, he should also sleep out of doors, or at least in a room to which the outer air has free access. Recent work in this direction has shown that the night air in this climate has no injurious effects, provided that plenty of bedding is supplied. The various forms of out-door treatment are well illustrated by this exhibition, so that it is unnecessary to enter into details.

There is one point, however, which is of great importance, and frequently neglected. This is the out-door treatment of bed-ridden patients, for whom it presents almost the only hope of recovery. It can be easily carried out by providing a veranda, which connects into the ward by means of a door opening even with the floor. The beds can then be rolled out with the patients in them.

The rest treatment is equally important with the fresh air cure; with few exceptions, all patients with fever should be kept in bed until the evening temperature is normal. It is, therefore, necessary that the temperature of all patients should be taken daily; if this can be done but once, it should be between 3 and 6 p.m., the time when the temperature is most likely to rise. After the patient is free from fever, it is

still necessary to continue the rest treatment, but in a modified form. He is now to be up, but should spend most of the day in a reclining chair. The amount of exercise should be increased very gradually, as a return of cough and fever is almost sure to follow over-exertion.

The stronger patients may be given light out-door work to do, but only after they have been free from fever for a considerable time.

The drug treatment of tuberculosis is of secondary importance. The specific treatment with the various forms of tuberculin has not yet given sufficiently brilliant results to make its general adoption in public institutions advisable. Creosote and its derivatives probably act solely by improving appetite and digestion, and should be used only so long as they have this effect. Other drugs are to be employed according to the symptoms; in general, the fewer the better.

To sum up the whole matter in a few words, the treatment of tuberculosis in public institutions should aim to approach that in use in modern sanatoria, and it is only by the use of such methods that success can be attained.

THE SUPPRESSION OF TUBERCULOSIS IN OUR DAIRY HERDS.*

BY AUSTIN PETERS, M.V.C.S.,

Chief of the Cattle Bureau of the Massachusetts State Board of Agriculture.

I HAVE been asked to make a few remarks upon the eradication of tuberculosis from dairy herds, more especially from herds owned by our public institutions.

Until within a few years the tubercle bacillus of cattle was supposed to be identical with that of man, but more recent researches made by Theobald Smith, Koch, and others have shown that there is a difference between the bovine tubercle bacillus and the human sputum bacillus. Evidently they are varieties of the same germ, modified by a vast number of generations of cultivation in different hosts. These changes are so marked that it is highly probable that they have become permanently fixed.

The sputum variety has but little virulence for cattle and other animals, while the bovine species seems to be very virulent towards cattle and other animals. As the sputum bacillus is virulent to humans, it is assumed that the bovine form is of little danger to mankind, in comparison to the views held a few years ago. This seems to be borne out by experience, as authentic cases where human infection can be traced directly to the use of meat and milk are very infrequent, and phthisis does not seem to be any more prevalent among men who work in cow barns than in ordinary pursuits. However it must be remembered that the development of tuberculosis is very insidious and that a person may not show evidences of the disease for some months or possibly even years after the infection. The disease remaining latent in some remote lymphatic

* Read at the Tuberculosis Exhibition, Boston Hotel, Jan. 6, 1906.

gland for a long period, and developing later under favorable conditions, thus making it impossible to trace the source of the infection in many instances.

It is a well-known fact that the milk of cows suffering with tuberculous udders, or with extensive tuberculosis even when there are no lesions of the udder, is capable of conveying the disease when fed to calves, pigs, and small experimental animals, and such milk is certainly unfit for human food when used uncooked, as demonstrated by the experiments of Ernst, myself and others. While sterilized milk is safe as far as its power to convey tuberculosis is concerned, it is less digestible for infants and invalids. Hence the milk from such cows should be prohibited as an article of food:

The importance of the matter of a healthful milk supply must not be overlooked in the consideration of other matters of greater importance in connection with this meeting. Admitting even that bovine tubercle bacilli in milk make it more palatable and nourishing than it otherwise would be, and that their presence is not harmful, there still remains the commercial aspect; with contagious pleuro-pneumonia, foot and mouth disease, and rinderpest, Walley includes, among the four bovine scourges, tuberculosis, which causes a large annual pecuniary loss to cattle owners, and for this reason should be diminished to the greatest possible degree. The herd of a public institution in Massachusetts that is not infected to a greater or less extent with tuberculosis is the exception, and not the rule, there being hardly any that have not suffered to a considerable amount from this scourge.

One great obstacle to keeping them in a state of freedom from this malady seems to be a lack of fixity of purpose. These institutions have their boards of trustees and superintendents, and occasionally a new trustee will be appointed, or a new superintendent take charge, who will insist upon cleaning up the herd; but with a change in the personnel of the board of trustees, or a change in superintendents, conditions lapse into what they were prior to making the attempt, matters become as bad as before, and the money expended is found to have been simply thrown away.

Numerous instances might be given where within a few years herds belonging to some of our state and city institutions have been freed from tuberculosis, under state supervision, and at the state's expense, tuberculin-tested cows placed in new barns, or in the old barns after thorough disinfection; but in a few years because of failure to test the animals once or twice a year, and carelessness in the purchase of new cows, the infection is reintroduced and the herd again becomes a tuberculous one.

While these efforts are spasmodic and sporadic little benefit will result; it is only a continued, systematic, definite purpose that will avail. With tuberculin as a diagnostic agent, it is perfectly possible to eliminate diseased and infected animals from the herd, and with thorough disin-

fection and the purchase of only tuberculin-tested animals, and a tuberculin test every spring and fall, a healthy herd can be maintained. A practical method of immunization of cattle to be introduced into herds where tuberculosis exists or has existed is also greatly to be desired.

Koch, von Behring and others have done work in this line, and von Behring claims to have discovered a satisfactory method. So far, it has only been applied to calves to be raised in herds where tuberculosis exists. Young calves receive an intravenous injection of a certain quantity of an attenuated human tubercle culture, and in three months a second dose five times the size of the first is given in the same way. It is claimed that calves thus treated are immunized for a considerable period, two or three years; whether this immunity lasts for the natural length of the animal's life it is yet too soon to say. This method may in time prove of great value to farmers, especially to breeders of pure bred stock owning herds in which tuberculosis exists.

If a similar method can be applied to older cattle about to be introduced into dairy herds where tuberculosis is present, it may prove of great benefit. New purchases after being tested with tuberculin and found to be free from tuberculosis can be placed in a quarantine stable and immunized before being introduced into the herd. Such a plan, if it proves practicable, would be of great assistance towards the eradication of this disease from herds which depend upon the purchase of new milch cows to replenish the stock rather than raising young animals for this purpose.

Many of the cows used in Massachusetts are brought here from without the state, and the regulations of the Cattle Bureau of the State Board of Agriculture require all these animals to pass a satisfactory tuberculin test before being placed upon the market, reacting animals being killed. About twenty thousand head, equal to 10% of the milch cows in Massachusetts, are thus tested annually, but in a few years many of these undoubtedly develop tuberculosis, and are killed and paid for by the state.

As far as the public health is concerned, milk consumers in this state receive a certain amount of protection, as the Cattle Bureau kills twelve or fifteen hundred head yearly that show marked physical evidence of disease or that have tuberculous udders, and such animals are the chief sources of danger; but much of the milk used comes from New Hampshire and other states to which this protection does not extend.

A little work is done by the Cattle Bureau in assisting owners to free their herds from disease, but a great deal cannot be undertaken in this direction because of limited appropriations, and much depends on individual effort, which does not seem to appeal to any great extent to the average farmer.

At present the chief work performed by the state is confined to killing the worst cases, and insuring as far as possible a market from which purchasers can obtain healthy cows if they will

buy animals that have come from out of the state.

If time permitted, a word upon the sanitation of stables would not be amiss, but all that can be said here is that they should be light, well-ventilated, well drained and clean, but this alone is not sufficient without the aid of tuberculin; and, if one is discovered, a practical method of immunization. Without means of immunization, however, tuberculosis can be eradicated from a herd with the aid of tuberculin and proper methods of disinfection and management.

DAY SANATORIUM FOR CONSUMPTIVES, PARKER HILL, BOSTON.*

BY DAVID TOWNSEND, M.D.,
Physician in Charge

THE Day Sanatorium, or Camp, for Consumptives was founded by the Boston Association for the Relief and Control of Tuberculosis. The camp was modeled after similar ones in use abroad, especially in Berlin, and was, I believe, the pioneer one of its kind in this country. This camp was purely a day camp, that is, the patients came in the morning, went home in the late afternoon.

The spot chosen, which the Association was enabled to obtain through the courtesy of the Robert B. Brigham Hospital trustees, was an orchard, a part of an old estate on top of Parker Hill, about 220 ft. above the sea and within three miles of the State House. This contained about $1\frac{1}{2}$ acres.

Living tent and kitchen.

The equipment of the camp consisted of a large mess tent, 20 ft. x 50 ft., with a board floor used as a dining tent and a shelter in stormy weather. In this were the tables (covered with white oil cloth easily cleaned) and settees. At one end was the staff table and a table for books, magazines and games. There were three smaller wall tents, 10 ft. x 12 ft. each, one for the care taker, who spent his nights on the premises, one for the administration tent in which were the scales and other necessary implements; and one for a store house for the couches and bedding.

* Read at the meeting of the Suffolk District Medical Society, Oct. 28, 1905.

chairs. The kitchen was practically a "lean-to" built against a barn and open to the north, with curtains for use in stormy weather. One half of this was boarded in for a pantry and contained the ice chest, milk cooler and household stores; the other half contained the sink, boiler, range (where all the meals were prepared) and the patients' dishes. Over the kitchen was the tank which held about one hundred gallons. This supplied a sanitary, established near by, and the boiler. It was connected with the city water supply. The tank had to be kept filled by a

Immunization and care taker's tents.

pump as we were above the limit of the city's low pressure service. The sanitaries and sink emptied by a drain into the city sewer, some 200 to 300 ft. away. In addition there were two benches with basins, one for the men, one for the women, where they washed, and the sputum incinerator, which was simply a cast-iron ash barrel.

The staff consisted of a matron, who was a trained nurse, an assistant nurse, a night watchman, a cook, a cook's helper and a physician. All save the physician received salaries.

The camp was opened July 6, 1905, and closed Oct. 31, 1905, practically seventeen weeks. The aim of the camp was to accomplish the maximum of good with the minimum of expense. Its chief object was the education of the patient in the care of himself and of his sputum, to prevent spread of the disease. We had as few rules as possible and tried to relieve the patients from all sources of worry. Each patient was seen alone, by the matron, every morning, and any worry or anxiety willingly listened to and the cause removed, if possible. The daily capacity of the camp was 50 to 60 patients, but on only comparatively few days did we have 50 or above.

The patients who applied for treatment came either through the various hospitals or through private physicians. Cases at all stages were taken, the only point insisted upon was that they should not be so far advanced as to be unable to walk down the hill to the cars at night. The cases were for the most part of the second and third stages. The patients came each morning by the electric cars from various parts of the city in

few were from the surrounding towns) to Roxbury Crossing, about three quarters of a mile from the camp, and were brought up by a park wagon which made four trips (8, 8.45, 9.15, 10). On stormy days the wagon was not sent, but those who could walk up the hill were gladly welcomed. At the outset only 4 or 5 could, without injury to themselves, walk up the hill; at the close 15 to 20 could easily do so. The patients were weighed on entering; this meant body weight; the women were weighed with a sheet $1\frac{1}{2}$ lbs. The patients were weighed once a week, chest examined once a month and pulse and temperature taken twice a day and recorded as long as they remained. This was all done in the administration tent. Any patient with a temperature 100° or above, and a high pulse, or who showed general weakness was kept on a couch, at rest, so long as these symptoms persisted. At the outset a good percentage required rest treatment; at the close only two, and these were recent acquisitions.

"Taking the cure."

The principal rule was, that under no consideration should a patient expectorate upon the ground; disregard of this meant reprimand; persistence, dismissal. Only twice this summer was it necessary to reprimand a patient for expectorating on the ground. Each patient on arriving was furnished with a small brown paper bag and squares of Japanese handkerchiefs for his sputum. The women had small chatelaine bags. These were of two parts, the outer was of denim of various shades of blue and brown, and the inner of stork sheeting, easily removed and sterilized. The outer portion could be washed and ironed, thereby sterilized. They carried their sputum bags with the moist paper, in the inner portion, and the spare papers and whatever they wished, between the inner and outer portions. Each portion was closed by a draw string. These bags were to be carried at all times. The cost of each bag was thirty-five cents and each woman patient was charged twenty-five cents or that portion which she could afford. Some could pay nothing. The sputum bags were placed in the incinerator at night and burned; a fresh supply was issued each night for use at home. On entering, the

patients were furnished with a piece of soap and a towel. These were kept in pasteboard boxes (which were donated); no box was used by more than one patient and they were kept in a closet for the purpose, outside the kitchen. The towels were washed on the grounds and a fresh one was issued each day. Blankets were provided for the cooler days.

For exercise the women set the tables and cleared them after dinner, the men wiped dishes, which were first placed in boiling water, washed, rinsed in hot water and wiped. The knives were washed and cleaned after each meal. For the rest of the time the patients sat about in reclining chairs, read, played games, or amused themselves as they wished. Books, games, magazines and daily papers were donated. The city opened a park surrounding a nearby supply reservoir, for a promenade, and this the patients greatly enjoyed.

At 9.45 to 10 the patients had a lunch of milk and bread and butter. Eggs and eggnoggs (without stimulants) were furnished for those who needed them. As 12 they had a dinner, and at 4 a lunch similar to the morning one. On colder days the milk was heated and just enough cocoa added to flavor it. They had meat four times a week, fish twice and fricasseed fowl once. In addition they had some form of potato, another vegetable, a wholesome dessert, preferably made of milk and eggs, and milk every day. Each patient consumed three to four pints of milk a day. No medicine was used except for obstinate cough, dyspepsia, constipation or diarrhea. We depended on fresh air and diet for our results.

There were 128 cases at the camp during the summer. The ages varied from 8 to 64 years and the majority were men. There were 69 males, 59 females. The ages were as follows:

Eight years, 1; 10 to 20 years 19; 20 to 30 years, 44; 30 to 50 years, 55; 50 to 64 years, 9.

We have had Irish, Germans, Russian Jews, Italians, Chinese, English, Americans, white and colored, French Canadians and Swedes. The length of time the cases remained was as follows:

Less than 1 week, 34; 1 week, 6; 2 weeks, 10; 3 weeks, 9; 4 weeks, 6; 5 weeks, 7; 6 weeks, 8; 7 weeks, 9; 8 weeks, 4; 9 weeks, 6; 10 weeks, 4; 11 weeks, 5; 12 weeks, 4; 13 weeks, 5; 14 weeks, 2; 15 weeks, 5; 16 weeks, 3; 17 weeks, 1.

The slightly advanced cases would not remain as they felt they were too well. The average daily attendance each month was as follows:

July, $27\frac{1}{2}$ +; August, 36 +; September, $32\frac{1}{2}$ +; October, not quite 35.

The attendance in July was less as our camp did not fill up immediately, and in September the low average was due to the number of rainy and threatening days we had. The greatest attendance on one day was 54, on Aug. 18. Sunday always had a smaller attendance.

There was a noticeable improvement in eating and sleeping, and diminution in night sweats from the start. The decrease in coughing, expectoration, and the improvement in the general condition, pulses and temperatures was most marked

after Sept. 1. There were 78 cases which remained 3 weeks or more at the camp (three weeks was considered a suitable basis from which to draw deductions); of these, 59 gained from $\frac{1}{2}$ to 20 $\frac{1}{2}$ lbs.; 19 lost from $\frac{1}{2}$ to 9 lbs. The maximum gain was 20 $\frac{1}{2}$ in 17 weeks, the maximum loss was 9 lbs in 9 weeks. Other gains were 16 $\frac{1}{2}$ lbs., 11 $\frac{1}{2}$ lbs., in 4 weeks, 10 $\frac{1}{2}$ lbs. in 7 weeks, 14 $\frac{1}{2}$ lbs. in 8 weeks, 11 $\frac{1}{2}$ lbs. in 9 weeks, 11 lbs. in 11 weeks, 15 $\frac{1}{2}$ lbs., 12 $\frac{1}{2}$ lbs. in 12 weeks, 12 $\frac{1}{2}$ lbs. in 13 weeks, 15 lbs in 15 weeks and 10 $\frac{1}{2}$ lbs. in 16 weeks. Fully one third showed some improvement in lung condition and will be able to pass a more comfortable winter. Some 5 or 6 will be able to do light out-door work this winter, more probably will do so, but ought not. Ten cases were sent to the State Sanatorium at Rutland, 9 of whom went; some were accepted before coming to us and were awaiting a vacancy; some were refused and then, after remaining with us a short time, were accepted. One case improved so much it was not considered necessary for her to go to Rutland. Two cases improved sufficiently so that they could go home to Ireland. There has been only one hemorrhage case and he had four at the camp, all comparatively slight, and for the last three weeks of his stay (until the camp closed) no blood at all. He was having hemorrhages when he entered and was taken in order to remove him from his unfavorable home surroundings. He was sent and returned each day by his employer. There were several cases of streaked sputum. One case developed a pneumothorax and was sent to a hospital.

As one would naturally expect from this class of cases, 3 became too ill and were sent to a hospital; 9 died at home, 8 from the disease and 1 from other causes (he was improving as to his lung condition).

The cost of the camp was about \$1,300, namely, fixtures and furniture. The cost of the maintenance of the camp was about 60 cents per day, per patient, for 40 patients, and this is reduced 12 $\frac{1}{2}$ cents per day, per patient, if you exclude the cost of the wagon. The camp was supported by voluntary contributions; each patient paid 25 cents per day or that fraction which he could afford. About one seventh paid something, while the majority were not able to pay more than their car fares.

The efforts of the physician and nurses were largely devoted to the instruction of the patient in preventing the communication of his disease to others, and every detail of the camp life on this side was watched with the greatest care. During the summer several simple talks on hygiene were given by one of the physicians from the tuberculosis department of the Boston Dispensary. Such a camp as the above is in no way to be compared with a properly equipped sanatorium, but it admirably supplements the treatment given at home by physicians or the hospitals to a large class of consumptives who cannot be in a sanatorium.

I am indebted to Dr. F. R. Tower and Dr. G. W. Hall and to my nurses for their valuable

assistance, and especially to my matron, Miss S. F. Robbins, to whose excellent management and kindly interest in the patients, the success of the camp was in a large measure due. I also desire to express my appreciation for the kindness which the Boston Dispensary showed us in furnishing the record blanks and in willingly filling prescriptions, thereby enabling the patients to obtain their necessary medicines at a small cost, or free if they were unable to pay. The consulting staff of the Camp was Dr. E. O. Otis, Dr. F. I. Knight and Dr. H. C. Clapp.

Clinical Department.

A REPORT OF SEVENTEEN CASES IN OPEN-AIR TREATMENT FOR SURGICAL TUBERCULOSIS IN CHILDREN.*

BY JOHN D. ADAMS, M.D., BOSTON.

Much has been said and written relative to the open-air treatment for tuberculosis, and we are justified in claiming its efficacy from the success already attained in the many sanitariums established throughout the country. The satisfactory results of these institutions for the treatment of tuberculosis in general have given us the assurance to try the same thing for surgical tuberculosis, which I think we may consider to be a local manifestation of a constitutional disease. I shall not attempt a paper on the subject of "Surgical Tuberculosis," which was so completely discussed in Dr. H. L. Burrell's recent article on the subject, and which did so much to stimulate us to our present work. It is only very recently that such work has been begun with children, and this paper is offered supplementing the foregoing article, merely as a report on seventeen cases in the convalescent stage of hip and spinal tuberculosis taken at random from the wards of the Children's Hospital.

Six of these cases were complicated with abscess, opened and drained.

All but three were able to be up and about with apparatus; these three were on go-carts.

All showed diminished hemoglobin ranging from 5% to 25%, a general condition very much below par, manifested by loss of flesh, indifferent appetite, lack of energy and absence of satisfactory improvement in local condition, those with abscess formation showing the characteristic persistent sinus with profuse discharge.

So far as was possible the cases selected were those which had been under treatment for periods varying from six months to a year or more, showing the indifferent unsatisfactory results obtained by the ordinary methods we are obliged to pursue with the poor ignorant patients, who, by force of circumstances, surround the children with conditions most favorable to the growth of the tubercle bacillus.

The mere suggestion of exposing such children, ranging from four to twelve years, to the cold

*Read at the meeting of the Suffolk District Medical Society, Oct. 28, 1905.

air, and obliging them to sleep in a temperature of 20° met with the severest opposition. But suffice to say that plans for a so-called "shack" were submitted and accepted, and in December, 1904, a building of the following brief description was completed at Wellesley Hills, eight miles out of Boston.

The building is 40 ft. x 20 ft. supported on cedar posts 2 ft. from the ground, double floor, with heavy paper between the floors, 8 ft. studding to the first pitch in the roof, which was approximately 9 ft. Rising from this perpen-

dicularly was a 2-ft. studding, which supplied a row of windows on either side. Another 4-ft. pitch to the ridge pole finished the roof. This roof was shingled with paper underneath. The sides of the building were fitted with sliding doors which made it possible to open 20 ft. of either side at a time. These doors were supplied with windows as were the ends. A 10 x 6 room, fur-

nished with a glass door, was partitioned off at one end to enable the nurse in attendance to sit and be comfortable. The windows at the top were so arranged as to prevent any direct draught. The building had a capacity for twenty cots, and the temperature was regulated to 20° by two ordinary coal stoves. The children at night were supplied with sleeping bags and flannel nightgowns with caps attached and draw strings at the bottom. It was specified that the children should have no medicine, live on a plain, whole-

some diet, and subjected to continuous treatment for from six to eight weeks. They were under the careful observation of the Drs. Dane, Stone and Thorndike, whose directions were most carefully and efficiently carried out by Miss Brooks, the superintendent of the Convalescent Home.

The following results shown in the accompanying chart, for which we have to thank Dr. F. H. Lamb for his careful and efficient work, shows the composite curve of the weekly records taken by him.

On admission the following points were noted: (1) General condition (color, appetite, activity); (2) weight; (3) hemoglobin; (4) local condition (chiefly as to sensitiveness of hip or spine and as to condition of sinus, if any).

The curve below represents the increase in weights, the one above the increase in hemoglobin.

It will be noted that in the weight curve we have a very rapid rise in the first two weeks, which is to be explained by the rapid gain of one case of sixteen pounds in two weeks. I think that we are justified in saying that the average gain in both weight and hemoglobin is very satisfactory considering the short time and the character of the cases. A careful analysis of the results shows the depressions in the curve were caused by the slow gain in those cases complicated with abscess and the three on the go-carts, and it is interesting to note that in three instances we were obliged to send cases to the hospital for surgical interference in the sinuses, and on return the records show a very perceptible loss in both weight and hemoglobin, while at the hospital for a period of a week, which fact would, of course, bring down our average. We, of course, have no way of recording the improvement in general and local condition, and that you will be obliged to accept my personal statement for. We have no hesitation in saying that every case showed the most gratifying results as to appetite, color and activity. And in one case a persistent sinus closed completely and remained

so. We also found that the abscess cases gained in hemoglobin, but very little in weight, showing the constant drain of a discharging sinus.

We were fortunate in having one of the severest of New England winters. The first night the thermometer dropped to 5° below zero, but I am happy to say that we had no frost bites. It was extremely gratifying to see the eagerness with which the children accepted this as a novelty, and we were flooded with volunteers for the "shack." The mental condition is always an important factor in the treatment of this disease, and the child's ignorance of its true condition, together with its resources for amusement, are important aids and prove the child to be a well adapted subject for this form of treatment. The children had a moderate amount of sunshine, but no special attempt was made to get it; and I might say that with reference to sunlight, while in Porto Rico this winter, I was struck with the prevalence of tuberculosis among the natives, who live in the open air and bask in the sunlight all day. This to me is satisfactorily explained by the fact that at twilight they shut themselves up ten or twelve in a dirty, filthy hut, absolutely devoid of fresh air.

I think we may draw the following deductions from our investigation:

(1) That the results are sufficiently gratifying to adopt the shack treatment for the basis of our new convalescent home, where we shall have a capacity for one hundred and fifty children.

(2) That in the past we have been prone to treat our cases too much like "hot-house plants"; that a constant supply of fresh air is an essential factor in the treatment of surgical tuberculosis; in other words, they should be exposed for the full twenty-four hours.

(3) That sunlight is an aid, but not an essential.

(4) That the average case should be subjected to this treatment for a period of not less than six months to produce satisfactory results.

(5) That ambulatory cases do better than inactive, and that those complicated with abscess should be carefully watched, drained freely and subjected to more prolonged and strenuous treatment.

(6) Climate is no specific, as we had tuberculosis in the cold north and in the tropics.

(7) That this treatment is only for convalescent cases and not those in the acute stage, as shown by the lack of improvement in the more acute cases.

In conclusion, we might say that these results are corroborated by the enthusiasm of the parents in each case over the improvement in their children, and we constantly hear the appeal of "When will you send my child to the shack?"

I fully recognize the incompleteness of this report, and we have failed to record many points which our limited quarters prevent us from so doing; but I see no reason why this work should not open up a large field for the treatment of all convalescing children, with a depleted general condition, and solve a heretofore difficult problem at a minimum of expense.

Medical Progress.

RECENT PROGRESS IN LARYNGOLOGY.

BY A. COOLIDGE, JR., M.D., BOSTON.

(Concluded from No. 2, p. 46.)

THE RELATION OF ASTHMA TO DISEASE OF THE NOSE.

A discussion of this subject in the British Medical Association was opened by Macdonald.¹⁰ In his paper he says that while we believe that asthma of long or short duration is often cured by treatment of the nose, we can neither ourselves offer explanation of the fact nor can the physiologist help us. Even if the latter can artificially excite symptoms of asthma by stimulation of the mucous membrane, he brings us no nearer a working theory and adds little or nothing to the value of our clinical observations. That the removal of any obstruction whatever in the nose or naso-pharynx may result in the cure of asthma whether spasmodic or catarrhal is well substantiated. The most favorable form of obstruction is hypertrophy of the erectile tissue especially the anterior extremities of the inferior turbinates. Also some cures have followed the removal of an irregularity of the septum causing pressure or obstruction to easy breathing. Less favorable than these in regard to the results of treatment is the affection called adenoids. Although asthmatics with polypi are greatly relieved by operation, and their general condition improved, the prognosis as regards their asthma is singularly uncertain, especially when polypoid degeneration has involved the ethmoidal region. Where there is no obstruction the treatment of unhealthy mucous membrane may help cure the asthma. In the case of edema the galvanocautery may be used with good results, especially over the upper part of the triangular cartilage.

In hay fever and hay asthma, even when there is no edema, good results may follow the cauterization of this region. The author was inclined to agree with the observations of Francis, that most cases of asthma were benefited by cauterizing this region, even when the nose is apparently normal, although it may first be necessary to remove some obstruction.

West¹¹ was by no means so optimistic, and agrees with the experience of Sir Felix Semon, that though relief may be given in a few cases, the prospects of cure are small.

Francis¹² argued that it is not yet known how far or in what manner a nasal lesion is responsible for asthma, and consequently progress in treatment is slow. It is uncertain whether good results are due to the restoration of normal breathing, or to the removal of sensory irritation. Asthma is comparatively rare in cases of marked nasal obstruction, while the majority of patients suffering from asthma have their noses in a fairly normal condition. Asthma is sometimes aggravated by a return to free nasal breathing, or

¹⁰ British Medical Journal, Nov. 5, 1904.

¹¹ Journ. Laryng. & Rhinol., 1900, Vol. 10, p. 100.

¹² Ibid.

by the removal of polypi. He is confident that the chief reason why operators so frequently fail to relieve asthma is that the one idea of treatment is to remove an irritation causing the asthmatic condition. He believes all asthma depends upon a condition corresponding to that inhibition of exchange which is dependent upon the respiratory center, and the stability can be affected by nasal treatment. Otherwise, it is hard to understand how gastric, cardiac, hereditary and other apparently characteristic forms of dyspnea can be relieved by nasal treatment or why these results are most easily obtained when the nose is apparently normal.

HAY FEVER ANTITOXIN.

During the two years in which the antitoxin of Dunbar has been in the market, no unanimity of opinion as to its value has been attained; neither has the theory of the etiology of the disease upon which it is based received due consideration. The original antitoxin was produced by the injection into horses of a toxin derived from the pollen of the gramineæ.¹³

In a recent address Dunbar,¹⁴ in addition to reviewing the subject of this antitoxin, describes his present position in regard to the American or autumn form of hay fever. The European hay fever he considers the same as that which in America is called rose cold or the June form, both of which he thinks are due to a toxin contained in the pollen of grasses. These do not bloom in August, whereas the rag-weed and golden rod, purely American flowers, have long been suspected of being the irritating cause of this autumnal catarrh. Some persons suffer both in spring and autumn, but in most cases the periodical attacks are limited to one season. The author has found an albuminous substance in the pollen of rag-weed and golden rod, which is probably identical in the two, but differs from that of the grasses. With this toxin he has been able to produce the characteristic symptoms in Americans who suffer from the autumnal hay fever, while it is innocuous in others. In Europe, also, some persons are affected by it, although never having lived in the neighborhood of the flowers they have never had autumnal catarrh.

From this toxin an antitoxin was produced. The author himself, having always had violent symptoms of hay fever when in America in August, proved the efficacy of this antitoxin upon himself recently while in this country. Why the toxin of hay fever should react with certain individuals and not with others is, so far, a matter of speculation only. The author appears to doubt the cases which react in a similar manner in the presence of horses and cats, and to think that these animals have in some way covered themselves with pollen.

THE INVOLUTION OF THE PHARYNGEAL TONSIL.

The disappearance of the pharyngeal tonsil is the subject of a paper by Goerke,¹⁵ who concludes

that involution takes place when the function of the gland has become superfluous. It is not in itself a process which confers immunity nor is it under normal conditions associated with any pathological processes, but it may be looked upon as the result of an immunity which has been acquired in other ways against certain diseases, especially the infectious diseases of childhood. The histological changes consist in the disappearance of the functionally active elements, the follicular tissue. After the involution we find the histological appearance of normal mucous membrane. Failure of involution is the result of past or present inflammation of the mucous membrane of the upper respiratory tract, and especially of the tonsil itself. The microscopic appearances of adenoid vegetations in adults differ from those in the normal pharyngeal tonsil in changes dependent upon these inflammatory processes. As we are not able to bring about involution of this structure in adults by conservative methods, it should be removed by operation.

THE FUNCTIONS OF THE TONSILS.

A contribution to this subject by Wood¹⁶ records the result of his microscopic study of the tonsils, and contains some interesting suggestions based thereon. The tonsils in common with all adenoid tissue, hold the property of producing lymphocytes in the secondary nodes or follicles. It occurred to the author that it might be possible that the tonsil not only reproduces lymphocytes by division of the old or mother cells which have migrated from the blood vessels into secondary nodes, but that this organ gives rise to original or young leukocytes by metachemism, that is, it forms them out of other tissue. Is it possible for the epithelium lining the crypts of the tonsil to be directly converted into leukocytes? The author believes that this question is to be answered in the affirmative. The strongest argument against the theory of leukocytic primogenesis as the function of the tonsillar structures of the throat is that the idea is too revolutionizing. It suggests the possibility of interchange of cell types; that no distinct line can be drawn between the epithelial cells, connective tissue cells and endothelial cells. As far as the tonsils are concerned if we accord to them the function of leukocytic primogenesis their presence in the human economy is beautifully explained. The leukocytes are intimately connected with various tissue changes, and the tonsils are largest and most fully developed at the time of life when tissue change is most active, namely, in childhood. The thymus gland developing early in embryonic life gives rise to the first leukocytes, and as this gland atrophies the tonsillar tissues develop, carrying on its function. Also it seems very possible that all adenoid tissue which has developed in intimate relation with epithelium is playing a rôle very similar to that accorded the tonsils. May it not be that the solitary follicles of the gastro-intestinal tract, the adenoid tissue of the appendix, and like struc-

tures are carrying on the work in the adult which the tonsils of childhood had usurped from the thymus of prenatal life.

HEMORRHAGE AFTER TONSILOTOMY.

This is a subject of interest to all who may be called upon to operate upon the tonsils. Serious bleeding either at the time of the operation or at varying intervals after, is common enough to deserve and to receive consideration in our textbooks and literature. Without offering anything new Heuking¹⁷ draws conclusions from his own experience and from recently published lists, especially from a series of 150 cases collected by Damianos and Hermann. Among the causes often ascribed for hemorrhage the author believes that hemophilia, or wounding of either carotid or an anomalous vessel, are very rare causes of this comparatively common accident. The tonsillar artery is seldom injured nor even its larger branches, unless the extirpation is very radical. Obstinate bleeding seldom comes from the stump of the gland, but generally from some wound of the anterior or posterior pillar. In the majority of the author's cases the upper portion of the posterior pillar was the source of the bleeding. This is accounted for by the fact that in gagging the posterior pillar is pushed into the guillotine. This instrument has the disadvantage that the cutting is seldom done under as accurate observation of the parts as with other instruments. After tonsilotomy a patient should be kept for a considerable time in a sitting position and no fluids collecting in the throat should be swallowed. In regard to treatment the author is surprised that such means for stopping the bleeding as astringent and cauterizing fluids and powders should be so often recommended, or complicated and difficult manipulations such as suturing or the use of elaborate instruments. The most satisfactory method is by digital compression.

The bleeding point should first be found and it can then be controlled with certainty. In rare cases it may be necessary to take more radical measures, such as tying of the carotid, but generally the bleeding will stop within a few minutes under light pressure with the finger wrapped in gauze.

PHARYNGO-MYCOSIS AND HYPERKERATOSIS.

In a thesis on the mycoses of the upper respiratory tract Sendzick¹⁸ discusses the different opinions on the etiology of the condition commonly known as pharyngo-mycosis or more recently as hyperkeratosis lacunaris. The latter name was suggested by Siebenmann who considered that a cornification of the lacunar epithelium was the primary condition and limited the role of the *Leptothrix buccalis* in the disorder to that of a simple saprophyte. To this the author does not agree but believes that it is a typical mycosis caused by this organism. The localization is principally in the crypts of the tonsils, it may, however, occur anywhere in the upper respiratory

tract. The author does not believe that treatment is superfluous, but recommends puncturing the crypts with a sharp cautery, and the application of trichloroacetic acid.

The opposite view is upheld by Onodi and Eutz.¹⁹ If we consider that the leptothrix grows in every throat and that it is especially luxuriant when the epithelium is pathological, also that all attempts at transplanting the disease have failed, it is probable that the plant has pathological properties. In substituting the name "hyperkeratosis" it is true that the etiology still remains in doubt, although not more so than in a similar disease of the skin.

Onodi believes that his work shows that Siebenmann's theory, that the cornification of the epithelium is the essential process, is maintained, but suggests that for the less marked cases the word "keratosis" might be substituted.

STOVAIN.

Dubar²⁰ recommends the use of stovain as a local anesthetic. He has found it effective, and superior to cocaine in being non-poisonous and cheaper. It is best used in from ten to twenty per cent solution in water or solution of bicarbonate of soda. It has been said to dilate the blood vessels, but the author has not found this to be the case.

Reports of Societies.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

THIRTY-FIRST ANNUAL MEETING, HELD AT INDIANAPOLIS, IND., OCT. 10, 11 AND 12, 1905.

THE president, DR. BRASSFORD LEWIS, of St. Louis, Mo., in the chair.

Addresses of welcome were delivered by MAYOR JOHN W. HOLTZMAN, on behalf of the city of Indianapolis, and by DR. W. N. WISHARD, on behalf of the local profession, which were responded to by DR. H. O. WALKER of Detroit.

The scientific work was divided into two sections, medical and surgical.

SURGICAL SECTION.

SURGICAL DRESSING.

DR. CARL E. BLACK, of Jacksonville, Ill., presented a preliminary report on the technique of the after-dressing of surgical cases. He pointed out briefly the principal elements necessary for the proper dressing of a wound, whether it be a surgical or an accidental wound. While the technique differed somewhat in different kinds of wounds, the fundamental principles were the same in all. Such a consideration divided itself into

1. The patient. Certain modifications must always be made to suit the individual case. 2. Those things which were auxiliary to the dressing itself, but which did not come in contact with the wound. 3. The surgeon or nurse making the dressing and his or her assistant. 4. The instruments, dressings and solutions coming in contact with the wound. Septic wounds should be so dressed that there was no opportunity for a further mixture of infection with the wound.

¹⁷ *Archiv. für Laryngol. und Rhinol.* 1904, 17, 105, 1.

¹⁸ *Journal. Laryngol., Rhin. and Otol.*, Nov., 1905.

¹⁹ *Archiv. für Laryngol.* 4, 1905, 10, 255.

²⁰ *Progress Med.* 5, 26, 1, 1905.

nor any opportunity for the infectious material from the wound to in any way be scattered where it could come in contact with other wounds. These two points should always be the basic principles of a surgical dressing, and should always be kept prominently in mind by those undertaking the dressing of wounds. To facilitate dressings and to economize in materials, and at the same time carry out a thorough technique, the author had arranged and had been using for some time a plan which had proved quite satisfactory. He had devised a box which contained everything that might come in contact with the wound, and everything, excepting the instruments, could be purchased in ordinary stores of towns and were not expensive. This plan was described in detail.

DR. JOHN YOUNG BROWN, of St. Louis, Mo., thought the secret of the success of the essayist in dressing wounds was due largely to the thorough system he had inaugurated. System was everything in surgery, as in business.

DR. O. H. ELBRECHT, of St. Louis, Mo., said the sooner surgeons reached a standard in the sizes of dressings, in tapes, squares, oblongs, etc., the less confusion there would be on part of the surgeon in going from one hospital to another to do surgical work. He mentioned the plan adopted by him in the hospital with which he was connected.

DR. C. E. RUTH, of Keokuk, Iowa, said that the sooner the profession came to a realization of the needs pointed out by the essayist, the less confusion there would be, as well as lessening very materially the liability to infection.

DR. MILES F. PORTER, of Fort Wayne, Ind., said the keynote of success in the management of surgical cases was system and simplicity. One should attempt to do away with the necessity of dressing wounds until they were healed in all cases where this was possible. The essayist spoke of there being no necessity for dressing an aseptic wound until the stitches had been removed. The speaker said there should be no stitches to remove in the ordinary aseptic wound, no matter where it was located, and in the ordinary treatment of septic cases the rule, as it prevailed in his judgment, made necessary a great deal more subsequent dressing than was called for. The dressing of a wound after it was made should be looked upon as an evil to be avoided as far as possible. He illustrated this point.

Dr. Black, in closing, said that the gist of the whole matter was system for the purpose of saving time, of safety for the patient, and for the purpose of economy.

CURETTAGE IN SEPTIC CASES.

DR. C. E. RUTH, of Keokuk, Iowa, stated that prevention must always be the most important treatment and must always include hygienic asepsis of the patient and physician and great care in examination. No instrumentation in any variety of puerperal sepsis should be considered which denuded the uterine mucosa and opened up tissues not in any sense protected from septic infection, the utmost gentleness being used to avoid any possibility of puncturing the softened or disintegrated uterine wall. The curette should never be used in such cases, certainly not a small or sharp one, and then only in the least serious of these cases, namely, saprophytic intoxication, which was not sepsis. He had for many years been satisfied with a placental detachor of his own device, which answered every purpose with a minimum danger of perforation. Streptococci and staphylococci were the most serious of puerperal infections, as these, on the manifestation of symptoms, passed beyond all possible reach of removal by any form of curettage. While curettement could do no good, it might do much harm in disseminating

infection and in causing uterine perforation. Within the last two and a half years the author had operated upon four cases of puerperal sepsis which illustrated the dangers of curettage. These cases were reported in detail.

DR. O. H. ELBRECHT, of St. Louis, Mo., thought that many deaths were due to the curette being used in cases of septic uteri. It was just as criminal, in his judgment, to introduce a curette into a septic or infected uterus as it was a sound or curette for the purpose of producing criminal abortion. He mentioned one case in which a physician curetted a uterus contrary to his advice, and the next day the patient died. He mentioned two other cases of sapremia that terminated fatally from what he believed to be curettement of the uterus.

DR. H. O. WALKER, of Detroit, said the paper was timely, and one could not condemn too strongly the indiscriminate use of intra-uterine curettes and irrigators. Many deaths were undoubtedly due to the indiscriminate use of these instruments.

DR. JOHN YOUNG BROWN said that while the indiscriminate use of the curette was dangerous, it nevertheless had an important function to fulfill. Where there were decomposing membranes or fragments of retained placenta, the uterus should be cleaned out.

DR. HANNAH M. GRAHAM, of Indianapolis, related her experience in treating the class of cases under discussion. She used an applicator, and not a sharp or dull curette. Cotton was wrapped around the applicator, which was saturated with carbolic acid, and the debris left in the uterus was swabbed out. It was her practice, too, to use a fenestrated catheter as a drainage tube, through which peroxide of hydrogen was injected every two to three hours, either by herself or the nurse, and she had had good success by this method.

DR. A. M. HAYDEN of Evansville, Ind., concurred in the remarks of Dr. Brown. When a physician was called to see a patient whose uterus contained a broken-down fetus or fragments of placenta, if he failed to clean out that uterus he thought he was criminally negligent. Patients went on for weeks with elevation of temperature due to sepsis, and would not get well without the judicious use of the curette, while if the uterus was cleaned out the patients would recover in a short time. He advocated the use of placental forceps for removing debris or pieces of retained placenta without disturbing or breaking down nature's protection.

DR. THOMAS B. NOBLE, of Indianapolis, uttered a word in defense of the uterine curette, saying it was an instrument for prevention as well as cure. The proper way was to interpret the pathology that one had to contend with, remembering that the curette was a means to an end. If a woman was suffering from high temperature, rapid pulse, prostration, due to saprophytic material in the uterus, which could be removed by mechanical means, the physician did her an injustice if he left the uterus alone, simply trusting to the *vis medicatrix nature* to take care of it.

DR. G. FRANK LYDSTON, of Chicago, said he did not believe that the essayist, nor those who spoke so emphatically in condemnation of the curette, would fail, as a matter of practice, to differentiate between the post-abortive septic phenomena met with and the post-puerperal septic phenomena. He did not believe that any of the gentlemen intended to convey the idea that the curette was to be condemned and never to be used. If one were called to see a woman who had been suffering from general sapremia for several weeks, who was in such a condition that it was evident dissolution was not far away, if something was not done, if the history was such that material had been left behind in the uterus, and she was having a temperature of 106°, he

would certainly not treat such a woman surgically or provide drainage by way of the vagina through the medium of vaginal irrigation, but would remove the septic material from the uterus. If this were not done the case was doomed, and many women in such a condition recovered under proper intrauterine treatment.

Dr. A. H. Ferguson, of Chicago, mentioned a case that terminated fatally on account of meddlesome interference on the part of a physician.

Dr. Ruth, in closing, said he thought a good deal of the discussion arose from a misunderstanding or failure to differentiate between the different varieties of infection that one had to deal with. There was no danger from a careful curettement in a case of putrescent uterus in which there was not added to the intoxication or septicemia a septicemia.

ARTIFICIAL HYPEREMIA IN SURGERY.

Dr. ALEXANDER C. WIENER, of Chicago, pointed out the indications for this treatment in surgery, as follows:

(1) Subacute mild inflammations of joints and soft tissues were relieved rapidly. (2) Acute purulent inflammations of soft tissues either on the extremities or the head. (3) Acute and subacute inflammations of joints and purulent arthritis; gonorrheal infection of joints. In these cases the elastic bandage had to be applied in such a manner as to produce energetic venous stasis, without causing pain to the sufferer. In acute inflammations comparatively light constriction produced an immense hyperemia. This conclusively showed that the arterial blood was not diminished but slackened. Cases were cited in which excellent results were obtained by the Bier method.

SURGERY OF THE GALL BLADDER AND ITS DUCTS.

Dr. H. O. WALKER, of Detroit, Mich., related his experience with 185 cases upon which he had operated. He quoted from a former paper written by him years ago, saying that what he said then still obtained to-day. *First*, jaundice, which heretofore had been regarded as almost pathognomonic of the presence of gall-stones, was present in only about 20% of all stone cases. *Second*, that pain in the region of the gall bladder did not by any means indicate the presence of gall-stones, but was quite as often the result of a kinking of the cystic duct from lesions the result of one or more attacks of cholecystitis combined with pericholecystitis. *Third*, the passage of stones in the biliary was not as common as was formerly supposed, for colics were rarely successful in passing a stone from the gall bladder. *Fourth*, empyema of the gall bladder was not always felt by palpation, for frequent attacks of cholecystitis tended to diminish the size of the gall bladder. *Fifth*, tumors of the gall bladder without pain or jaundice indicated a simple dropsy, while a painful, distended gall bladder indicated empyema, and when accompanied by jaundice indicated constriction of the choledochus. *Sixth*, a hard, nodule, painful tumor of the gall bladder, with or without jaundice, was almost certain evidence of carcinoma. *Seventh*, obstruction of the choledochus, accompanied with inflammation and jaundice, quickly disappeared after the passage of the stones into the papilla of the duodenum.

Cholelithiasis was of greater frequency than was supposed. Approximately every tenth individual had concretions in the gall bladder, yet only about one in twenty ever complained of their presence, so that most stones needed no treatment. It was only the cholecystitis and cholangitis which made manifest the irritable presence of gall stones without demanding treatment, namely, medicinal and surgical.

The conditions that required operative intervention were: (1) An acute sero-purulent cholecystitis and

accompanying pericholecystitis. (2) Persistent and frequent pains due to adhesions between the gall bladder, intestines, stomach and omentum. (3) Chronic obstruction of the common duct. (4) Chronic empyema of the gall bladder and its accompanying accidents.

Cholecystectomy was undoubtedly advisable where the gall bladder had been subject to frequent attacks of inflammation, and where chronic septic conditions existed.

The author reported an interesting case in which he removed the gall bladder and fixed the right kidney.

RETROPERITONEAL TERATOMA.

Dr. C. M. NICHOLSON, of St. Louis, Mo., read an interesting paper on this subject.

The tumor described was a teratoma of the abdominal cavity, remarkable not only because of its rare occurrence, rapid growth, and total absence of symptoms until three weeks before death, but because with its substance had been found a chorion epithelioma. The following is a report of the author's case:

Aug. 5, 1905, he was consulted by C. W., a healthy-looking, well-developed young man, twenty-one years of age, who complained of one symptom, fainting, which had occurred twice during the preceding week. He had attended to his business until Aug. 4, when he quit work, fearing an accident during his trips as superintendent down in the mine. Upon inspection, the abdomen appeared normal; pressure over the region of the gall bladder enabled the examining finger to outline a pear-shaped body. In the median line beneath the rectus abdominis, extending from a point four inches above the pubes to the lower margin of the right lobe of the liver, was an immovable mass of definite form. The line of dullness was continuous between the pear-shaped body and the mass in the median line. Although the growth measured four inches in width, no intestinal disturbance had resulted. Three weeks later patient vomited and complained of great pain after eating. The vomiting became more frequent and the pain more severe with each succeeding day. He saw the patient Sept. 3, and the following morning made an exploratory incision, revealing a growth extending from the right kidney to the last dorsal vertebra, thence downward to within two inches of the pubes. It was firmly attached to the median line posteriorly and to the kidney externally. The posterior peritoneum was cut through and the mass found to be enclosed in a fibrous capsule, which was sewed to the anterior layer of the peritoneum and a portion of the growth removed. The patient sat up at the end of the first week, but continued to complain of great pain. He died two weeks after the operation.

Post-mortem examination was made by his assistant, Dr. S. J. Stahl, whose report in part was as follows: "On opening the cavity of the abdomen and cutting through the posterior peritoneum and fascia transversa, a fibrous capsule enclosing a semi-solid mass and adherent only in the median line and to the right kidney, was found. Not without much difficulty could the tumor be removed, so intimately was it attached to the structure anterior to the vertebral column. The abdominal aorta from the first dorsal vertebra to the fourth lumbar was closely attached to the growth. The gall bladder was distended evidently due to pressure on the common duct. Neither the lumbar glands nor the kidneys were enlarged, although the right kidney was adherent to the tumor. The liver, though very slightly enlarged, showed evidence of involvement. The heart and pericardium were normal. The lungs contained two or three lined nodules."

The tumor weighed a little less than two pounds. It was right-angled and lobulated, the lobules being smooth and extending in different directions. On cutting, the tumor was soft, the anterior inferior extremity being partially cystic. Some of the cysts were as large as a hazel nut. The remainder of the growth appeared solid. The outer surface of the tumor was covered with a distinct fibrous capsule. Paraffin section of the Zenker fixed tissue showed a very complicated mass. Portions of organs were found corresponding in embryonic origin to all the germinal layers. Skin, cutaneous organs, central nervous system, peripheral nerves, represented the epiblast. Mucous glands, tubes, cysts with epithelial lining, were indicative of the hypoblast. Bone, cartilage, fibrous tissue, constituted the mesoblastic structures.

The author considered at length the different theories advanced in the past to account for the origin of teratomata.

DR. JOSEPH RILEY EASTMAN, of Indianapolis, said he had had a remarkable experience in relation to tumors of this character. He had had two cases of complete precececal teratomata, but he had not had such a case as the one related by Dr. Nicholson. The speaker's cases were simply instances of precececal teratomata; they were not cases of inclusio fetalis which Dr. Nicholson had reported. In the first there was presented the clinical picture of a complete external fistula in ano. Long hairs protruded from both orifices, but when the roof of the canal was split up it developed that there was quite a cavernous space there which was lined with epithelial membrane, and this proved to be in either case a precececal teratoma or dermoid.

Dr. Eastman related a case in which his father had removed almost a complete skeleton from the abdominal musculature of a man in middle age.

Dr. Nicholson, in closing, stated that chorion epithelioma occurring in a case of retroperitoneal teratoma was extremely rare, and so far as a search of the literature was concerned, he had been unable to find a similar instance. Examination of the microscopic slides demonstrated clearly the presence of tissues from the three germinal layers.

SOME OF THE FALLACIES IN THE CLINICAL DIAGNOSIS OF GONORRHEA.

DR. G. FRANK LYDSTON, of Chicago, discussed some of the more dangerous of the fallacies in the diagnosis of gonorrhea, with especial reference to prognosis as regards the infectiousness of a given individual to other and healthy persons with whom he or she might come in sexual contact. He considered, first, the possibility of excluding infectiousness in the case of a woman under suspicion, or who was known to have had gonorrhea. That the most dangerous type of infection of the female was that in which the external manifestations of the disease were absent, or wanting, was coming to be well understood by both gynecological and genito-urinary specialists. The explanation of the relatively great danger of infection of others by such subjects was not so thoroughly understood as it should be. Gonorrheal urethritis in the female, when it had assumed the chronic form, might present no secretion whatever upon external examination. There might be little or no vaginal, cervical or uterine discharge, and even such as there was might upon examination fail to disclose the micro-organisms of gonorrhea. A swab or probe passed into the urethra might return perfectly clean. Notwithstanding this apparent lack of infection in the urethra, the mucous glands might be involved, and under the influence of

sexual excitement and the mechanical effect of coitus the physiological hypersecretion might convey to the meatus gonococci in abundance. The result was sufficiently obvious.

The author presented clinical facts which would seem to make it impossible for a physician to state in any given case that a woman was free from infection. This was one of the strongest arguments against regulation and medical inspection of prostitutes. He entertained serious objections to the medical profession constituting itself an assurance society for the protection and promulgation of the social evil, but aside from this scruple, there remained the fact that no reliable system of inspection or examination could be devised.

The author was firmly convinced that in many cases of infection of healthy women by a latent gonorrhea of the husband, mixed infection was responsible, and the resulting pathological condition in the female was non-specific. Its being non-specific, however, did not preclude the possibility of its becoming very serious.

The author thought that we had no tests at the present time which would enable us to give a positive opinion of the infectiousness of a given case of suspected latent gonorrhea. As already suggested, the clinical history in many cases was more important than the laboratory study of the case, and a careful combination of both methods of study was always essential. The physician should be as chary of assuming responsibility in advising a gonorrheic in the matter of matrimony as he should be in advising syphilitics under similar circumstances.

DR. W. E. WASHBURN, of Kewanee, Ill., exhibited an improved urethrotome.

(To be continued.)

Recent Literature.

The Diagnostics of Internal Medicine. A Clinical Treatise upon the Recognised Principles of Medical Diagnosis, Prepared for the Use of Students and Practitioners of Medicine. By GLENTWORTH REEVE BUTLER, Sc.D., M.D., Chief of the Second Medical Division, Methodist Episcopal Hospital; Attending Physician to the Brooklyn Hospital; Consulting Physician to the Bushwick Central Hospital, etc. Second revised edition. Illustrated. New York and London: D. Appleton & Co. 1905.

Butler's work appears in its second edition with certain minor alterations in the text and changes in the illustrations. The book in general remains one of the best types of modern work both as regards text and clearness of illustration. Diagrams are freely used and every effort has been made in this, as in the previous edition, to render clinical signs and symptoms realistic by graphic means. In this attempt the matter of illustration has been somewhat overdone, particularly in the use of photographs of a female model to illustrate various pathological points which could be done as well by a less striking form of illustration. The book will no doubt continue to occupy a useful place among its many allied treatises on the same general subject.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, JANUARY 18, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico. \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE, Incorporated,
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

THE RELATION BETWEEN EDEMA AND THE
ELIMINATION OF SODIUM CHLORIDE.

It has become pretty well established, since the work of Widal and Juval in 1903,¹ that there is a close relation existing between the edema of certain forms of nephritis and the elimination of sodium chloride. The two forms of kidney disease in which edema is a very prominent feature are acute and chronic parenchymatous nephritis, and in these two diseases there is sufficient pathological change in the cellular portion of the kidneys to interfere with the elimination of solids, particularly sodium chloride. The theory of Widal and Juval was that when there is a retention of sodium chloride, the salt retained in the tissues requires a certain amount of water to maintain proper molecular concentration and dropsy results. This explanation of the cause of edema in nephritis is a plausible one and is worthy of much consideration.

Authorities agree that only a small amount of salt is essential to health and that amount is approximately 2 to 5 gm. The majority of people take from 10 to 20 gm., and those with the "salt habit" take 30 to 40 gm. Koziezkowsky found that although there was a wide variation in the output of sodium chloride in perfectly healthy persons—varying from 6.8 to 11.4 gm. in one case and 9.9 to 24.7 gm. in another—where they were given an additional 10 gm. of salt for three consecutive days there was a retention of it varying from 18 to 25 gm. in the twenty-four hours. There is, therefore, apparently a fixed relation existing between the intake and output of sodium chloride for each healthy in-

dividual. Accepting the theory of Widal and Juval of the cause of edema in cases of kidney disease, then any sodium chloride which cannot pass through these diseased organs will call for sufficient water to establish proper molecular concentration in the tissues.

When persons with an acute or chronic parenchymatous nephritis ingest more salt than their kidneys will eliminate, there is generally a perceptible gain in weight—accompanying the increased dropsy—apparently the direct result of the retention of a large quantity of water. The albuminuria becomes intensified and there are finally all of the symptoms of an impending uremia. In the experiments of Widal and Juval, they were able to cause an edema to appear or disappear at will by increasing or withdrawing sodium chloride from the diet of their patients.

We have added information upon this very important subject in a paper by Miller.² He studied two cases of acute nephritis, seven of chronic parenchymatous nephritis, one case of myocarditis and several patients with normal kidneys. His conclusions resulting from his observations are interesting and are as follows:

1 "In patients with moderately severe nephritis associated with edema, the ingestion of large amounts of sodium chloride is followed by a chloride retention. The patient gains in weight, the edema becomes more marked, the albuminuria increases and symptoms may develop resembling uremia."

2 "In patients with severe nephritis, and especially those with uremia, chloride retention is very marked, as scarcely any of the extra chlorides administered are eliminated."

3 "In individuals with apparently healthy kidneys, following the ingestion of sodium chloride, there is a chloride retention equal to that of mild nephritis. The individuals gain in weight but there is no visible edema, no albuminuria and no uremic symptoms appear."

The case of myocarditis with pleural effusion, ascites and general edema improved materially when there was an unusual intake of the salt, nothing was said as to the condition of the kidneys in this case but they were probably normal. This case of heart disease brings up the question as to the effect of chloride retention in cases of disease of the heart in which there is extensive edema and a mild or severe passive congestion of the kidneys but no primary nephritis. There is certainly an opportunity for research along this line and the results ought to be valuable.

¹ Presse Medicale 41.

² Journ. Amer. Med. Assoc., Dec. 1, 1903.

Observations thus far indicate that in disease of the kidneys which are associated with edema, the amount of sodium chloride ingested should not exceed 2 gm. per diem, and that intravenous and subcutaneous injections of normal salt solution should be avoided as a therapeutic measure in all such cases. Widal found that the edema disappeared and there was general improvement on a diet consisting of 400 gm. of meat, 1,000 gm. of potato, 100 gm. of sugar, 80 gm. of unsalted butter and 2,500 cc. of fluid, the whole containing only about 1.5 gm. of sodium chloride.

THE BOSTON TUBERCULOSIS EXHIBITION.

If publicity is to prove a valuable means of combating tuberculosis, there can be little question that the cause has been materially benefited by the recent tuberculosis exhibition held in Boston. Much time and thought had been expended by those in charge of the preparation of the exhibition with the result that a realistic exposition of the causes and means of prevention of the disease were given. The demonstration appealed to various classes in the community, and to persons with varying degrees of medical knowledge. The most ignorant, as well as the best informed, could not have failed to carry away some new knowledge from a few hours spent in the building. Realism was not lacking for the edification of those living in abject poverty, and the exhibition of the pathological anatomy of tuberculosis with the microscope demonstrations could not have failed to be instructive to the most advanced student of the subject. The painstaking care which had been so liberally expended in preparing the exhibition was rewarded by the somewhat extraordinary public interest which it aroused.

The exhibition was open to the public for eleven days of thirteen hours each, giving 143 as the total number of exhibition hours. During this relatively short period the entire attendance was 25,953, or an average each day of 2,359. It is also a noteworthy fact that interest increased during the progress of the exhibition. With but two exceptions, one of which was Sunday, the last day, each day showed an increase in attendance over its predecessor. The largest attendance was on Saturday, the day before the closing, with a total of 4,154. There is every reason to believe that this large attendance was representative, and that people from all parts of the city and from all classes of society, many from the suburbs, and in some instances persons from a distance

visited the exhibition. This was especially gratifying to the management, inasmuch as the main object of the exhibition was to reach the diverse classes in the community, all of whom have something to learn regarding hygienic methods of living. A feature of the exhibition, and one which, no doubt, added much to the lessons it taught, was a carefully arranged series of special meetings at which various physicians and laymen, who had knowledge of the various phases of the tuberculosis problem, addressed such persons as were present. The aggregate attendance at the lectures was 5,425. In addition to this seven lantern slide exhibitions were given, at which there was an aggregate of 2,625 spectators. In order to reach the non-English speaking part of the community a meeting for Hebrews was given, attended by 250, in which the addresses were made both in English and in Yiddish. Italian was also used in these lectures.

A comparison of the foregoing figures with those of the New York exhibition, held a few weeks previously, is interesting. Although the New York exhibition continued for fourteen days the attendance was 17,000, or a daily average of slightly more than one half of that in Boston. The reasons for this were due to many factors, one of which no doubt is that the reputation of the New York exhibition preceded that of Boston and that through the generous co-operation of the daily papers it was much more widely advertised. In all such attempts at educating the public in the future the assistance of the daily press should be sought, and we have no doubt will be gladly given. The success both of the New York and Boston exhibitions will doubtless lead to a repetition elsewhere of the same general plan. It is, in fact, announced that the money has been offered for such an exhibition in Springfield, Mass. Under proper direction, it would be possible and certainly desirable to reproduce such demonstrations, even in towns and villages. As a means of education it has certain definite advantages over spreading knowledge through pamphlets and leaflets.

MEDICAL NOTES.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Jan. 17, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 40, scarlatina 26, typhoid fever 5, measles 102, tuberculosis 36, smallpox 0.

The death-rate of the reported deaths for the week ending Jan. 17, 1906, was 18.14.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Jan. 13, 1906, was 198, against 232 the corresponding week of last year, showing a decrease of 34 deaths and making the death-rate for the week 17.35. Of this number 89 were males and 109 were females; 192 were white and 6 colored; 128 were born in the United States, 63 in foreign countries and 7 unknown; 45 were of American parentage, 130 of foreign parentage and 23 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 43 cases and 3 deaths; scarlatina, 31 cases and 1 death; typhoid fever, 11 cases and 5 deaths; measles, 118 cases and 3 deaths; tuberculosis, 41 cases and 15 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 15, whooping cough 0, heart disease 15, bronchitis 9 and marasmus 3. There were 7 deaths from violent causes. The number of children who died under one year was 40; the number under five years, 66. The number of persons who died over sixty years of age was 42. The deaths in public institutions were 58.

There were 3 cases and 2 deaths reported from cerebrospinal meningitis during the week.

A CENTENARIAN. — Hiram Warren of Springfield, Mass., died Jan. 14, at the reputed age of one hundred and one years.

APPOINTMENTS. — Dr. Edward S. Smith of Westfield has been appointed associate medical examiner of the Fourth Hampden District. Dr. John E. Magrath of Hudson has been appointed associate medical examiner of the Ninth Middlesex District.

THE PREVALENCE OF OLD AGE. — It is reported from the town of Barnet, Vt., which has a population of about eighteen hundred, that at the beginning of the year there were thirty-seven persons in the town over eighty years of age, in the proportion of twenty-five women to twelve men.

THE DISMISSAL OF DR. BOWDITCH FROM RUTLAND. — We have received from Dr. J. P. Rand, Secretary of the Board of Trustees of the Rutland Sanatorium for Tuberculosis, newspaper clippings giving statements of the trustees in regard to the recent dismissal of Dr. V. Y. Bowditch, accompanied by a request that they be given the same publicity as was given to our editorial of Dec. 7. This request we cannot comply with for several

reasons: The statements have already appeared in full in the daily press (*Worcester Telegram?*), where those who are interested can read them. The statements themselves are somewhat contradictory. The subject is now under investigation by an official committee to which it has been referred.

PROCTOR HOSPITAL FOR INCIPIENT TUBERCULOSIS. — At a meeting of the State Tuberculosis Commission, held in Rutland, Vt., Dec. 26, the decision was reached that the state hospital for the treatment of incipient tuberculosis, recently provided for by a gift of \$100,000 from Senator Redfield Proctor, is to be located in Pittsford.

COMMITTEE OF THE MASSACHUSETTS MEDICAL SOCIETY TAKES ACTION. — As a result of a complaint which has been filed with the Massachusetts Medical Society, the Committee on Ethics and Discipline is investigating charges alleging unprofessional conduct on the part of two members of the society concerned in the recent notorious "suit case" trial.

PROTEST AGAINST THE DISMISSAL OF DR. V. Y. BOWDITCH. — A protest against the recent dismissal of Dr. V. Y. Bowditch as physician to the Rutland, Mass., Sanatorium for Tuberculosis, signed by nearly three hundred prominent physicians of the state, was handed to Governor Douglas shortly before his retirement from office, and passed on by him to Governor Guild. Governor Guild has referred the document to the Committee on Public Charities of the Council.

CEREBROSPINAL MENINGITIS AT THE NEWPORT TRAINING STATION. — Cerebrospinal meningitis has appeared among the naval apprentices at the Newport training station. Strict quarantine regulations have been adopted, affecting not only the apprentices among whom the disease first occurred, but extending to the entire sixteen hundred stationed at this post. Portable pavilions are to be used in the care of the patients, for which a liberal appropriation has been made.

BOSTON FLOATING HOSPITAL. The twelfth annual report of the Boston Floating Hospital summarizing the season of 1905, has been published. The year's work was most successful, even though conducted under the disadvantages of an inadequate boat. The plea is again made for a larger boat for the purposes of the hospital, which will undoubtedly be gratified, and plans are given in the report. This charity is a deservedly popular one and should receive general public support.

NEW YORK.

APPOINTMENTS. — At a meeting of the trustees of Columbia University, held Jan. 8, Dr. Frank W. Jackson was appointed Professor of Clinical Medicine and Dr. Walter F. Chappell, Clinical Professor of Laryngology.

APPROPRIATION FOR TUBERCULOSIS HOSPITAL. — At the first meeting of the new Board of Estimate and Apportionment, held Jan. 12, Health Commissioner Darlington secured an appropriation of \$70,000 for the expenses of the Mount Hope Tuberculosis Hospital in Orange County.

Obituary.
EMMET COOPER DENT, M.D.

DR. EMMET COOPER DENT, Superintendent of the Manhattan State Hospital for the Insane, Women's Department, on Ward's Island, New York City, died suddenly on Jan. 12. He was born in Macon, Miss., Oct. 11, 1859, and was graduated from Bellevue Hospital Medical College, New York, in 1879. At the time of his death he was secretary of the American Medico-Psychological Society and Professor of Mental and Nervous Diseases in the New York School of Clinical Medicine. Dr. Dent's untimely death will be a very severe loss to the service of the New York State hospitals. During his incumbency as head of the institution on Ward's Island he had done admirable work, introducing, with the most gratifying success, all the most approved modern methods in the treatment of the insane. As an adjunct to the regular treatment of his patients he secured the services of a number of the best New York specialists in various departments, so that very unusual advantages were enjoyed by the inmates of his hospital. Dr. Dent also possessed so many genial qualities that he endeared himself to all who were brought into association with him.

Miscellany.
PROSECUTION OF FRAUDULENT PRACTITIONERS.

On Jan. 12, Dr. William Wallace Hadley and Mrs. Laura M. Wilson, respectively medical director and assistant medical director of the "Force of Life Chemical Company," were arrested by the Federal authorities and held in \$2,500 bail each for future examination, on a charge of conspiracy to obtain money under false pretenses by the use of the United States mails. For the past three or four years this fraudulent concern has maintained elaborate offices on Broadway, New York, and has done a very large mail business. The County Medical Society, through its counsel, Messrs. Andrews and Cooper, and the United States authorities,

have co-operated in their efforts to bring to justice the chief offenders and put a stop to circulation of the literature of the company through the mails, and the prosecution will be conducted by Assistant United States District Attorney Houghton. The action on the part of the government is said to have been personally prompted by President Roosevelt, to whom some one sent a circular of the company, among the extraordinary statements printed in which were the following: "By his mysterious control over disease and death Dr. Wallace Hadley, the eminent thauumaturgic panoplist of this city, has made the human heart beat again in the body of a woman rescued from the grave. And as a result of his successful experiments he makes the startling statement that no disease should cause death. He claims to have discovered the vital principle of life itself, the dynamic force that creates and maintains existence. Since making this discovery the cures made by this man of science have been so remarkable, the restorations to life and health that he has brought about have been so marvelous, that he is credited with possessing some power over disease and death not given to ordinary mortals. He seems to have absolute control over human life and the diseases that attack it." In order to obtain evidence against the company a number of letters were sent to it from supposed patients, and the replies preserved for use in the prosecution. One of these supposed patients to whom the fictitious name of "Lucille Hoffman" was given, was asked to send a specimen of her blood for examination. Accordingly, Mr. Cooper procured some blood from a horse and forwarded it, and shortly afterwards received a letter which declared that the examination indicated such frightful physical conditions that he wondered how the poor horse could possibly survive for a day longer. "Lucille Hoffman," after having sent in \$6.00, the cost of a four weeks' treatment, and waiting for the specified time to elapse, wrote the company that she had not been benefited and claimed the privilege promised in all its literature and correspondence, of having her money refunded. In reply there came a letter telling her in learned medical terms that she was suffering from five other complaints with long and high-sounding Latin names. No money, or promise of money, however, came with the new diagnosis. Mr. Cooper states that while the company claims to have its own well-equipped laboratory and that its preparations are the discovery of Dr. Hadley, as a matter of fact the drugs dispensed by it are procured from a New York firm of manufacturing chemists. He has had an examination made of the medicines sent as the result of the correspondence with the supposed patients, and finds that the pills furnished cost about fifteen cents a thousand, while the entire outfit of medicine sent for \$6.00 can be procured for something like 36 cents. Dr. Hadley is a graduate of the medical department of the University of Buffalo and a registered physician, but the name of Mrs. Wilson does not appear in the list of registered physicians.

THE CARTWRIGHT LECTURES, 1906.

THE Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons of New York will be given on Thursday, Jan. 25, Monday, Jan. 29, and Friday, Feb. 2, by Baron Takaki on "Military and Naval Sanitation: Experiences Drawn from the Late Japan-Russia War." Dr. Takaki belongs to one of the samurai families of the Satsuma clan, as do his contemporaries, Generals Oyama, Kuroki, Nogi and Nodzu, and Admirals Togo and Kamamura. During his youth he was sent by his government to study medicine in England, where he graduated with honor from St. Thomas's Hospital School, studied the sanitary system of the British navy, and passed examinations for the degrees of F.R.C.S. and F.R.C.P.

On his return to his native country he directed his chief attention to reformation of the sanitary and medical systems of the newly born navy of Japan. It was not only reorganization that he accomplished, but the creation of an entire medical equipment and medical sanitary service for the Japanese navy. He was rapidly promoted to the rank of surgeon-general of the navy, which position he held until the time of the Japan-China war. At present he is in the Naval Reserve. As a recognition of his great services rendered to the Emperor and his country, he was created a Baron after the conclusion of the Japan-China war.

During his active service in the navy Baron Takaki initiated and carried out certain fundamental changes in the dietary and sanitary regulations of the navy which resulted in the almost total suppression of beriberi, which, up to that time, had seriously impaired the efficiency of the service, affecting annually almost one quarter of the navy's personnel. Baron Takaki also has been president of the Naval Academy of Japan, president of the Tokyo Charity Hospital, councillor of the Association for the Sanitary Improvement of Japan, and has held other important positions. He has been active in spreading the principles of the Red Cross Society in Japan, and it is to his efforts that the large number of Red Cross members in Japan is largely due.

Baron Takaki has received the honorary degree of Doctor of Medicine of the Japanese government, a degree issued only by the Department of Education and not the same as the degree of M.D. conferred on graduates of the University.

He is a member of the House of Peers of the Parliament of Japan, having been directly nominated by the Emperor.

ments of human effort, primarily from labor unions, a great number and variety of orders and societies, fraternal, socialistic, political, politico-religious, beneficiary, composing both sexes and all having certain characteristics in common. They appeal strongly to the *genius hominis*; he is gregarious, likes to flock, ever ready to try to get something for nothing while taking no risk. Most of these orders have as a part of this system a doctor who is known as the doctor of the order, and who contracts and agrees to treat each member of the order for a year for a certain insignificant sum which he receives from each member, whether they have called upon him or not. The question of admitting this class of doctors to the Berkshire District Medical Society came up at its last meeting, Dec. 28, 1905, when candidates came up for membership, but it was not discussed. It has seemed to many of the old time physicians that a doctor who contracts to treat professionally for a year a man or woman for \$1.50 to \$2.00 should not masquerade as a member of the ancient and honorable Massachusetts Medical Society. That the censors of each county should make it a bar to admission for the following reasons:

SOME REASONS WHY CONTRACT PHYSICIANS SHOULD BE EXCLUDED FROM THE BERKSHIRE DISTRICT MEDICAL SOCIETY.

1. The system violates correct medical ethics in that it is a close corporation, a combine between a physician and an order.
2. It tends to dwarf individual progress and independence in the physician himself.
3. It so cheapens professional learning that the community will question its existence.
4. It is a tacit confession of impunctuality and inferiority.
5. It results in a lowering of professional dignity and self-respect.
6. It is an unfair advantage over brother practitioners.
7. It is an aggravated form of commercialism that has no place in the profession of medicine.
8. The profession and practice of medicine never has been and never can be regulated and controlled by the same laws and methods that control trade, barter and sale.
9. The educated and cultivated physician of the past guarded with a jealous, watchful care the standards of professional excellence and character.
10. Its written code of ethics, a century old, is founded on the broad basis of equal rights and equal privileges for every member of the profession.
11. Its unwritten code is founded on the Golden Rule and is as old.

Very truly yours,

E. E. MARINE, M.D.

THE GIBBS MEMORIAL PRIZE OF THE NEW YORK ACADEMY OF MEDICINE.

New York, Jan. 15, 1906.

Mr. Editor.—In addition to and as a partial correction of the statements published in the early December issues (1905) of all the large medical weeklies of the United States concerning the Gibbs Memorial Prize Essays on the "Etiology, Pathology and Treatment of the Diseases of the Kidneys," the trustees of the New York Academy of Medicine beg leave to announce:

First. The prize amounts to two thousand dollars this time.

Second. The prize essays may be handed in October 1, not January 1, 1907, or before that date.

Third. The prize committee does not expect the etiology, pathology and treatment of the disease of the kidneys to be discussed with equal completeness. It will be satisfied with the thorough scientific consideration of part of the problem, provided an essay offers a conception containing new facts or discoveries or presenting a new or sufficient point.

For the New York Academy of Medicine:

A. JACOBI, M.D., *Chairman.*

A. M. JACOBI, M.D., *Secretary of the Trustees.*

Correspondence.

CONTRACT PHYSICIANS.

WHITTINGTON, MASS., Jan. 9, 1906.

Mr. Editor.—There has grown up within the last few years as a result or as an outgrowth of this era of combination, organization, unionism, in the various depart-

* NOTE.—The populations of the Massachusetts cities and towns are estimated from the rate of growth from 1900 to 1905. The figures for Lowell, Taunton, Gloucester, North Adams and Clinton were allowed to stand as in 1905, these places having shown no growth during the five-year period mentioned.

Deaths reported, 2,974; under five years of age, 825; principal infectious diseases (smallpox, measles, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption), 557; acute lung diseases 610, consumption 303, scarlet fever 19, whooping cough 13, cerebrospinal meningitis 19, smallpox 0, erysipelas 5, puerperal fever 11, measles 22, typhoid fever 23, diarrheal diseases 69, diphtheria and croup 67.

From whooping cough, New York 4, Baltimore 4, Boston 4, Holyoke 1. From scarlet fever, New York 13, Chicago 3, Baltimore 2, Salem 1. From cerebrospinal meningitis, New York 4, Baltimore 2, Boston, Worcester, Lynn, Lawrence, Woburn and Revere, 1 each. From erysipelas, Boston 4, Brockton 1. From typhoid fever, New York 11, Chicago 4, Baltimore 2, Providence 1, Boston 2, Lowell, Springfield and North Adams, 1 each. From measles, New York 16, Chicago 1, Providence 1, Boston 4. From diphtheria and croup, New York 50, Chicago 11, Boston 2, Cambridge, Salem, Waltham and Pittsfield, 1 each.

In the seventy-six great towns of England and Wales, with an estimated population of 15,699,377, for the week ending Dec. 30, 1905, the death-rate was 17.4. Deaths reported 5,199; acute diseases of respiratory organs (London) 241, whooping cough 91, diphtheria 69, measles 117, smallpox 0, scarlet fever 43.

The death-rate ranged from 7.5 in Kings Norton to 30.6 in Hanley; London 17.8, West Ham 13.3, Brighton 16.0, Southampton 14.1, Plymouth 18.5, Bristol 18.5, Birmingham 18.9, Leicester 17.1, Nottingham 15.7, Birkenhead 17.1, Liverpool 24.9, Wigan 16.9, Bolton 14.9, Manchester 19.4, Salford 16.7, Halifax 15.9, Bradford 16.0, Leeds 17.7, Hull 16.2, Sheffield 15.3, Newcastle-on-Tyne 22.3, Cardiff 13.6, Rhondda 19.2, Merthyr Tydfil 25.4.

METEOROLOGICAL RECORD.

For the week ending Jan. 6, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

RECENT DEATHS.

DR. FRANK PARKER PERRY of Bucksport, Me., died Jan. 13, at the age of fifty-five. He received his medical education at Bowdoin Medical School.

DR. HARRY A. MCGIBSON of Brooklyn, N. Y., was killed in an elevator accident on Jan. 12. He was thirty-five years old, and was graduated from the Illinois Medical College, Chicago, in 1898. At the time of his death he was assistant dermatologist in the Brooklyn Central Infirmary.

DR. SELWYN A. RUSSELL of Poughkeepsie, N. Y., died on Jan. 12, in the fifty-third year of his age. He was graduated from the Albany Medical College in 1877, and for several years served on the medical staffs of the state hospitals for the insane at Utica and Poughkeepsie.

DR. H. EUGENE PARK of Whitehouse Station, Hantardon County, N. J., died on Jan. 8, at the age of fifty-six years. He served for several terms as County Clerk, and at the time of his death was Fish and Game Warden.

APPOINTMENTS.

H. H. HASKELL, M.D., has been appointed ophthalmic surgeon at the Massachusetts Charitable Eye and Ear Infirmary.

F. H. VERHOEFF, M.D., has been appointed assistant ophthalmic surgeon at the Massachusetts Charitable Eye and Ear Infirmary.

BOOKS AND PAMPHLETS RECEIVED.

International Clinics. A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otolaryngology, Rhinology, Laryngology, Hygiene and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession throughout the World. Edited by A. O. J. Kelly, A.M., M.D., Vol. III, Fifteenth Series, 1905. Philadelphia and London: J. B. Lippincott Co.

A Treatise on Diagnostic Methods of Examination. By Prof. Dr. Hermann Sahli. Edited, with additions, by Francis P. Kinnicut, M.D., and Nathaniel Bowditch Potter, M.D. Authorized translation from the fourth revised and enlarged German edition. Illustrated. Philadelphia and London: W. B. Saunders & Co. 1905.

ON THE DEVELOPMENT OF SCIENTIFIC
HYDROTHERAPY.

BY JOSEPH H. PRATT, A.M., M.D., BOSTON.

*Physician to Out Patients, Massachusetts General Hospital; Assistant
in the Theory and Practice of Physic, Harvard University.*

THE NEED OF GREATER ATTENTION TO HYDROTHERAPY IN AMERICAN MEDICINE.

IN A paper I read before the Massachusetts Medical Society in 1904 the attempt was made to indicate the position held by hydrotherapy at the present time in the leading countries of the world.¹ My investigation included a study of the hydrotherapeutic facilities in some of the leading medical clinics of Germany, Austria, Italy and England, an examination of the amount and quality of hydrotherapeutic literature, a comparison of the leading textbooks in German and English with reference to hydrotherapy, and of the medical curricula of the different countries. It was perfectly evident from this inquiry that American medicine lags behind not only Germany and France, but all the leading nations except England. Scientific hydrotherapy will not be widely used in private practice until it is accurately taught in the schools. In 1902 thirteen out of the nineteen German universities gave special courses in physical therapeutics, many of which were devoted to hydrotherapy. In America, on the other hand, not one university gave a similar course.

In the introduction of that splendid system of medicine, "Die deutsche Klinik," Professor von Leyden describes the German clinic as it exists at the beginning of the twentieth century. It is significant that over half of this essay is devoted to therapeutics and attention is chiefly paid to methods of treatment without drugs. Modern therapy in Germany is becoming more and more to mean physical therapy, and of all the branches of physical therapeutics hydrotherapy has the widest field of usefulness. Von Mering's textbook of medicine indicates probably more accurately than any other work the position hydrotherapy holds in the university clinics of Germany. It is composite work prepared by fourteen of the leading medical teachers. In the first edition, published in 1901, there are references to many diseases in the index under "hydrotherapy" and "baths." In the third edition issued in 1905, all reference to hydrotherapy has been omitted from the index, and the word "bath" does not appear there. On examining the body of the work, the reason is evident, to have indexed all the diseases for which hydrotherapeutic procedures are recommended would have meant the enumeration of nearly every clinical condition described in the work. Hence, to mention hydrotherapy in the index would have been of no more value than to list all the cases for which pharmacotherapy was advised. Von Leyden said that the "dietetic and physical

therapeutic methods should be studied, developed, practiced and investigated." These words have evidently been heeded. Another quotation of von Leyden's that Bunn has selected as a motto for his "Lexikon der Physikalischen Therapie," indicates the direction of therapeutic development in Germany: "Physical therapy should be utilized not in the clinic alone, it must become the common property of general practitioners."

In America the influence of this new movement in therapeutics is yet scarcely apparent. Here diagnosis is still supreme. As in the days of Frerichs and Traube in Berlin, that physician is the most famous who can say to his students after an autopsy, "We have found everything exactly as we expected."²

The therapeutic movement in Germany began with the abandonment of the search for drugs of supposedly specific action. Many of our leaders have apparently believed with Dietl, the high priest of Nihilism, "that there are no true therapeutists, there are only optimistic physicians." The result has been that most of the physicians of this country can be divided into two groups, those whose therapeutic unlabeled or skepticism has led them to pay little or no attention to treatment, and, secondly, those whose reasonless faith accepts without question the claims of the exploiters of proprietary medicines.³ Doubtless the reason that hydrotherapy and the other forms of physical therapeutics are still looked upon with suspicion by our best physicians is due to the fact that they have received such scant recognition by the medical leaders and have been accorded such extravagant praise by irregular practitioners.

There are some indications that the dawn of a new and better day in American medicine is at hand. In a few schools demonstrations and special lectures on modern methods of treatment are given. Detotherapy based upon physiological laws is being studied, and instruction in pharmacology has replaced antiquated courses in materia medica.

Excellent works on hydrotherapy have been published and they are having an increasing sale. The admirable textbook on hydrotherapy by Dr. Baruch has been translated into German and honor rarely accorded to any American medical author.

THE PHYSIOLOGICAL BASIS OF HYDROTHERAPY.

The term "hydrotherapy" would denote the use of water in its three physical states—solid, liquid and gaseous. The water is used either as a medium for the conveyance of temperature. The greater the variation of temperature between the medium used and the body, the greater the effect on circulation. Although both cold and hot applications exert a thermic irritation on the skin,

1. Von Leyden. Die deutsche Klinik, p. 13. 2. Baruch. Hydrotherapie, p. 1. 3. A few hours after writing the above I received a letter from a leading pharmacologist. "I find it a pity," says the writer, "that in the United States, where therapeutics is so scientific and so much eliminated, we do not have a more rational and more well reasoned, which is necessary to the cause and restoring the natural alkalinity of the blood."

of the two is widely different. Mechanical irritation is frequently combined with thermic irritation in hydrotherapeutic procedures. The mechanical irritation is best exerted by the so-called "douche treatment." The essential feature of the douche treatment is the impact of a stream of water upon the surface of the body. By varying the pressure and temperature, the mechanical and thermic irritation may be increased or decreased as desired. In all treatments with cool or cold applications it is essential that a reaction should occur at the close of the treatment. By reaction is understood, a secondary dilatation of the cutaneous vessels following the primary contraction which the cold application produces. In order to insure a good reaction cold applications are almost always preceded by some heating procedure. In hydrotherapeutic insti-

fever, as Romberg and Pässler have shown that the so-called heart failure in acute infectious diseases is usually due to paralysis of the vaso-motor center. Cold baths stimulate the sensorium. This action was recognized years ago in the treatment of delirium and somnolence in fever. It is also seen in the feeling of well being induced by properly administered cold applications to persons in health. Lukewarm baths have a sedative action, and are one of the best means of overcoming insomnia.

Modern hydrotherapy is founded on the solid rock of physiological and pathological knowledge. The work of Wilhelm Winternitz should never be forgotten by students of hydrotherapy. His physiological investigations and those of his students rescued hydropathic treatments from empiricism and quackery. The physiological basis

Office and reception room of "The Medical Baths." This is a co-operative enterprise for furnishing hydrotherapeutic facilities to Boston physicians.

tutions, hot-air baths, vapor baths or light baths are generally employed for this purpose.

Exercise or massage is frequently of service in promoting a good reaction after a cold application. It will thus be seen that hydrotherapy is not employed alone, but is combined with thermotherapy, light-therapy and mechanotherapy. There is a widespread error even among physicians that hydrotherapy is limited to cold-water treatments. Other common misconceptions are that hydrotherapeutic treatments exert little or no influence on the body; that no matter how applied, they are harmless and act chiefly or entirely by suggestion. Investigation, however, shows that there are few drugs in the pharmacopoeia which, in therapeutic doses, have such an influence upon the animal economy. Cold water is the safest and the most powerful antipyretic. Still more important therapeutically is the stimulating action of cold applications on the vaso-motor center. This probably explains the beneficial effects of cold baths in typhoid

of hydrotherapy is well presented by Matthes in his textbook.⁴ Over one hundred pages are devoted to the consideration of the action of water treatments on the functions of the human body. Water exerts its most pronounced effect upon the circulatory, respiratory and nervous systems. Cold or hot irritation applied to the skin not only acts directly upon the surface treated, but reflexly through the central nervous system upon the circulation in other parts of the body. For example, if the hand be plunged into cold water not only the vessels of that hand become contracted, but of the other hand as well. It has been demonstrated that cold irritation of short duration applied to the feet of a rabbit produces contraction of the vessels of the pia mater. Of great importance therapeutically is the fact that the circulation in the abdominal organs is influenced by the application of heat or cold to the surface of the body (Brieger). Hydrotherapeutic procedures have a pronounced

⁴Matthes: Lehrbuch der klinischen Hydrotherapie, Jena, 1903.

influence on the blood pressure. Those irritants that cause a contraction of the vessels lead to an elevation, while those that produce a dilatation cause a sinking of the blood pressure. Hence, the general statement can be made that cold applications raise the blood pressure, while warm applications lower it.

The action of the heart and the frequency of the pulse are likewise influenced by thermic and cold irritants. Cold applied locally over the heart or to the entire body diminishes the frequency and increases the force of the cardiac contractions, while the warm irritant increases the pulse rate. Carbon dioxide baths exert the most marked effect on the heart. The minute carbon dioxide bubbles which cover the entire surface of the body act as powerful mechanical

long continued, diminish the sensibility of the peripheral nerves; and hence are of importance in stilling pain. The value of long-continued warm applications over the abdomen in cases of gastric or intestinal pain is probably due in large part to the resulting hyperemia of these organs. In certain cases the beneficial effect of hot applications to the abdomen in intestinal disease is due to the action of the heat irritant on the smooth muscle of the intestine, producing a lessening of peristalsis, and relaxation of the intestinal wall.

A single energetic hot air bath may lead to a loss of sweat amounting to more than a liter. In one of my cases it amounted to 1,500 grams. That this great secretion of sweat influences profoundly the whole circulation of blood and lymph is easily understood. It is of undoubted

A small treatment room

stimuli. In cases of dilated heart I have frequently observed a temporary reduction in the transverse diameter, as determined by percussion, amounting to 3 cm. or more. Cold procedures cause a local increase in the number of erythrocytes and leucocytes in the capillary circulation. Warm procedures, such as hot full baths, hot air and electric light baths, produce an increase in metabolism, especially in the breaking down of non-nitrogenous substances. In hot full baths this increase in oxidation has been shown to be more marked than that which occurs in fever. With the application of intense heat, especially if often repeated, there is increased destruction of albumin.

The sudden application of cold to the surface of the body, especially to the back of the neck, produces a deep inspiration, and at its height a pause. This is followed by deep respirations, usually of increased frequency. Heat irritation on the other hand, leads to respirations of increased frequency and generally of more superficial character. Both the cold and warm irritants

value in the elimination of morbid products. It has been shown that in renal insufficiency the abnormally high molecular concentration of the blood can be reduced by sweating and it has been recently found that in these cases the low nitrogen content as well as the molecular concentration of the sweat is considerably increased. The importance of the increased secretion of sweat in the elimination of various poisons, including lead, mercury and bacterial toxins, and in the elimination of pathogenic microorganisms, should be mentioned. The procedure, which elevates the blood pressure and increases the general circulation cause an increased elimination. This is especially marked after the administration of carbon dioxide. Not only the excessively cold procedures, but also the hot full baths, albumin and albuminuria.

HYDROTHERAPY AND AEROTHERAPY

In the treatment of a great number of diseases hydrotherapeutic procedures may be of great advantage. They should of course be con-

ployed in conjunction with drugs when drugs are indicated and are frequently of value combined with other forms of physical-dietetic treatment. Often hydrotherapy may be substituted for pharmacotherapy to advantage. A full tub bath at 90° Fahr. of fifteen to thirty minutes' duration is better than trional in insomnia, and hot compresses to the abdomen in gastric ulcer are preferable to morphine.

The great variety of effects produced by water of different temperatures should be specially emphasized. According to the temperature employed, the blood pressure may be raised or lowered, local congestion, or anemia produced, the pulse-rate increased or decreased, respirations quickened or deepened, and the action on the

clearly understood that it may have to be altered in a few days or possibly an entirely different form of treatment substituted in order to obtain the best results. Increased experience with neurasthenia has impressed me with the truth of Binswanger's dictum in regard to hydrotherapy in this disease, "that the success of any hydiatic procedure can never be predicted, and the individual reaction of the patient is decisive." I agree with v. Strümpell⁵ and Matthes⁶ that the water treatment in neurasthenia acts chiefly as a psychical influence. An electric light or hot air bath followed by a cool application usually gives rise to a general feeling of well being. This doubtless produces in many sick individuals a powerful *Heilsuggestion*. The benefit I have

The douche room of "The Medical Baths."

sensorium may be stimulating or depressing. In many incurable diseases properly selected hydrotherapeutic measures are distinctly beneficial. They make the patients feel better, eat better and sleep better. I believe that more attention should be paid to the treatment of this distressing class of cases. To keep a patient with inoperable malignant disease or chronic nephritis comfortable, or at least to make the downward journey as easy as possible is no small thing. Some hydiatic procedures are so mild that they may be given with benefit and without danger to very feeble patients.

The important place of hydrotherapy in the treatment of neurasthenia and in other psychoneuroses is so well known as to completely overshadow in the minds of many its other fields of usefulness. It is true, however, that hydrotherapy achieves equally good results in other diseases. The right selection of hydiatic treatment in neurasthenia is often difficult. No firm or fast rule can be followed with success. Every case must be individualized. If a hydrotherapeutic prescription is given it should always be

seen in many cases has been so marked and so sudden as to make this explanation the most plausible one. Good effects have been much more striking when treatments were carried out at the hydrotherapeutic institute than when they were given in the home of the patient. The action of the procedure on the body would be the same in the two places but the action on the mind might be very different. I have noticed that those neurasthenic patients have rarely done well whose physicians have had slight confidence in hydrotherapy or who revealed to the patients that they had had little experience with it.

NON-COMMERCIAL HYDROTHERAPEUTIC INSTITUTES.

In Boston a successful experiment has been made in professional co-operation. In the fall of 1903 a hydrotherapeutic institute was established by a number of physicians interested in

⁵ v. Strümpell: Die funktionellen Neurosen in Penzoldt-Stintzings Handbuch der spez. Therapie, Jena, 1903, v. p. 391.

⁶ Matthes: Lehrbuch der klinischen Hydrotherapie, Jena, 1903, p. 333.

the securing hydrotherapeutic facilities for the benefit of their patients. At that time the attention of the profession was called to this enterprise in the columns of this JOURNAL,⁷ and a plea was made for more attention to this department of therapeutics. The second year of its work has just closed and it is a pleasure to report that it has been a financial as well as a therapeutic success. During the past year the receipts from patients were \$3,986. This was sufficient to make the establishment self-supporting, and was a gain of 70% over the preceding year. Equally gratifying is the increase in the number of physicians who have referred patients to the medical baths, and the increase in the number of disorders that have been treated. At first we received neurasthenic and rheumatic cases almost exclusively. During the last few months

recently instruction in hydrotherapeutic procedures was given here to the Senior class of the Harvard Medical School.

This institute, or the Medical Baths, as it is called, has done much to give dignity to scientific hydrotherapy in this community. The establishment of similar institutions in other cities could not but help to develop interest in this important but much neglected form of treatment. The organization and the maintenance of such institutions should not be difficult in cities much smaller than Boston. Our institute is due almost entirely to the labor of Dr. James J. Putnam, who planned and initiated this movement, and whose continued support has rendered success possible. Two years ago at his suggestion, a meeting was called to consider "the practicality of maintaining a hydrotherapeutic estab-

Electric light cabinet. When the patient is seated on the stool and the apparatus closed the entire body with the exception of the head and neck is exposed to the radiant heat. Sweating more profuse, occurs at a lower temperature, and is givensooner than when a hot air bath is employed, and in muscular rheumatism and neuralgia the anæsthetic effect is more marked.

among the maladies treated have been cases of heart disease, chronic parenchymatous nephritis and chronic interstitial nephritis, obesity, arteriosclerosis, tuberculosis and severe cerebral and spinal diseases.

During the past summer it was necessary to close the establishment for an entire month in order to repair and renovate. A new cement floor was laid in the douche room as the tile floor previously used had given rise to troublesome leaks. At this time an original form of local hot air bath was added to the therapeutic equipment. It was decided before the institution was opened that it should be in no sense a commercial enterprise. It is intended that any surplus which may accumulate after the debts incurred in fitting up the establishment have been paid shall be devoted to increasing its facilities or in promoting the advance of hydrotherapy in various ways. Re-

lishment where private patients can be carefully treated and suitable researches carried on." On this occasion a committee, composed of Dr. J. J. Putnam, E. G. Cutler and R. W. Lovett, was appointed to assume charge of such an undertaking. Since the opening of the Medical Baths they have acted as its governing board. Dr. Putnam raised over \$34,000 for the equipment of the institute. Most of this sum of money was contributed by friends of Dr. Putnam outside of the medical profession. The physicians who subscribed to a contingent guarantee fund of \$2,000 included many of the ablest local physicians, at the large hospitals and teachers in the Harvard and Tufts medical schools.

Admirable quarters were secured on the upper floor of a modern office building. Plenty of light and sunshine was thus obtained. The rooms were attractively furnished. A complete Biers-Richter apparatus for douche treatment was installed. This form of douche table with a

⁷Putnam, BOSTON MEDICAL AND SURGICAL JOURNAL, January 1903, vol. 5, p. 746.
 Pratt, *Ibid.*, 1904, et. p. 288.

facilities for regulating exactly the different temperatures is probably equal to any in the world. In order to secure the proper water pressure so far above the street level it was necessary to add an electric pump to the equipment. Our operators have been thoroughly trained in the application of simple hydrotherapeutic measures as well as those that require elaborate apparatus. Hence, it has been possible to give all forms of hydropathic treatments. The establishment is under the immediate charge of a matron who has been with us from the beginning. She is on duty the entire day, and arranges the hours for treatment. Our plan of reserving a definite hour for each patient has proved an admirable one. From 9 A.M. to 1 P.M. women are treated, and the afternoon is reserved for men. Mr. Anderson and Miss Moran, our chief operators, are both graduates of the Posse Gymnasium, where they received a thorough training in mechanotherapy. As they only spend a half of each day at the Medical Baths, it has been possible for any physician in the city or vicinity to engage their services for the administration of hydrotherapeutic treatments in the homes of patients. Inasmuch as the number of persons in this section of the country who have mastered the technique of hydrotherapy in addition to massage and gymnastics is small, we consider that this is not the least of the benefits conferred by this institution on the community. The success attained by Dr. Putnam and his colleagues in this enterprise has led nearly every hospital in the city to formulate plans for adding a hydrotherapeutic department to their equipment.

REPORT OF ILLUSTRATIVE CASES.

The following cases which I have seen within the past year indicate clearly the beneficial results that may sometimes be obtained by hydrotherapeutic procedures alone and combined with other remedial agents.

CASE I. *Chronic parenchymatous nephritis; extreme anasarca; disappearance of edema; weight diminished 58½ pounds with gain in strength.* — Mrs. L., aged forty-five. She was referred to me by Dr. Daniel of Watertown. For a year there had been marked anasarca. Her abdomen had been tapped three times. Diuretics had been tried repeatedly but it had been found impossible to reduce the urine. I found 0.9% of albumin in the urine with hyaline and granular casts. At the time of my first examination, March 30, 1905, the face was puffy, the abdomen was distended with fluid, and the edema of the legs was so great as to produce an elephantine appearance. She weighed 188½ pounds. A "salt-free diet" with electric light and full-tub baths were prescribed. After four months' treatment there was only a trace of edema remaining. Her weight had been reduced to 130 pounds, a loss of 58½ pounds, with a gain in strength, and apparently a gain in flesh. There has been an increase in the amount of urine secreted. Her general condition is now very good. On Oct. 10, 1905, she weighed 129½ pounds. I attribute the remarkable improvement chiefly to the "salt-free" diet, but I believe the electric light baths to have been a valuable adjunct.

CASE II. *Coronary endarteritis; chronic interstitial nephritis; cardiac insufficiency; great improvement pro-*

duced by carbon dioxide baths and muscular exercise. Mrs. J., aged, sixty-six, was a patient of Dr. Cahill. She had been confined to the house for six months owing to shortness of breath. While spending a few days in Boston in the fall of 1904 she climbed two flights of stairs in order to visit her dressmaker. This exertion produced such severe dyspnea that the attempt had not been repeated. The apex beat was in the sixth intercostal space outside the mammillary line, and 13 cm. from the midsternal line. The cardiac outline was enlarged, chiefly to the left. There was a systolic bruit at the apex. The pulse was at times irregular and intermittent. The blood pressure at the first examination was 215 (Riva-Rocci, broad cuff). The urine contained a trace of albumin and an occasional hyaline tube-cast. The twenty-four hour quantity was only 385 cc.

In spite of the high blood pressure I advised carbon-dioxide baths, beginning with salt baths containing only a small amount of carbon dioxide.

She took twenty-eight baths and after the first week of treatment, graduated exercises. The blood pressure became permanently lowered. At the time she finished the course of baths, June 26, 1905, it was 165. The stronger baths produced a temporary reduction of 3 to 4 cm. in the width of cardiac dullness. During the last two weeks of treatment she frequently walked from the hydrotherapeutic institute to the Hotel Westminster, a distance of half a mile, without shortness of breath or other discomfort. Improvement continued and on Jan. 1, 1906, her condition is excellent, and she is able to take exercise.

CASE III. *Obesity, producing dyspnea and difficulty in walking, loss of 26½ pounds in two months with general improvement and gain in strength.* The patient, a woman, aged forty-eight, was referred to me by Dr. C. M. Hutchinson of Waltham. She had been slowly putting on fat for twenty years. For the past five years she has suffered from shortness of breath on exertion, which became so bad as to interfere with her work about the house. She was able to walk but little. When I first saw her on Sept. 14, 1905, the breathing was labored and accelerated, the effect of a short walk. She was a very obese, florid woman, weighing 256 pounds. The bony framework was small. The heart and kidneys were healthy. I prescribed a restricted diet and three electric light baths weekly, each of forty-five minutes' duration. On Oct. 16, she weighed 238 pounds, a loss of 18 pounds in a month. She had much less dyspnea and felt stronger and able to walk more. In addition to the baths and diet I now gave her Carlsbad salts and thyroid extract. On Nov. 20, the end of the second month of treatment, her weight was 229½ pounds, a reduction of 26½ pounds, with marked improvement in her general condition.

CASE IV. *Subacute rheumatism.* June 10, 1905. I saw to-day with Dr. Sheehan of Stoneham, W. A., aged twenty-two, who is troubled with lameness of the legs, stiffness of the neck, and pains in the muscles of the trunk, arms and legs. In 1901 he was confined to his bed three months with rheumatic fever. In 1904 he suffered from stiffness of the joints and muscular pain. Treatment at the Virginia Hot Springs resulted in a complete disappearance of symptoms. In January, 1905, the rheumatism returned and has persisted. The joints chiefly involved are the ankles and right wrist. At times the ankles are swollen. Stiffness has affected chiefly the fingers and spine. On May 1, he came from New York to Stoneham and placed himself under Dr. Sheehan's care. At that time his temperature was found to be 102½. He was put to bed and sweating procedures used. The fever soon left him.

Status praesens. The patient is a well built young

man. The complexion is pale and pasty but the hemoglobin is found to be 95% (Sahli). He walks with the aid of a cane. The neck is held stiffly and the right thumb is slightly swollen and its movement limited. Temperature 99°. Heart normal. I advised daily electric light baths and douches, Carlsbad salts, and a diet rich in fats and proteids.

June 23. Although the weather has been damp or rainy for a week there has been no return of pain or stiffness.

July 7. Feels perfectly well. He has taken twenty-two baths, and spends much time in the sunlight, as directed. He drinks from three pints to two quarts of milk daily with relish, and has gained eight pounds in weight. He had used a cane for a long time before beginning treatment, but discarded it about two weeks ago.

CASE V. *Insomnia of neurosthenia*. Mrs. K., aged forty-five years, seen with Dr. W. H. Howe, June 5, 1905. She had not been sleeping well for the past year. Last summer she spent several weeks camping out in the woods, but obtained no benefit. For the past four months she has had persistent insomnia and anorexia. She frequently does not fall into a sound sleep until five o'clock in the morning, and then awakes at seven. At the time Dr. Howe was first consulted she was taking a small amount of alcohol regularly before going to bed and a dose of trional about every other night. We advised daily treatments at the Medical Baths, consisting of an electric light bath and douches, for a month. Neutral baths at night were also prescribed. No hypnotics were used. She began to sleep well after the first week. She left for the country early in July and returned to town a month later in better condition than she had been for a long time.

CASE VI. *Severe neurosthenia of long duration*. Mrs. R., aged fifty-eight years, was sent to me by Dr. W. H. Baker in October, 1904. She stated that for twelve years she had been troubled with severe nervous prostration. She had tried all manner of treatment. At the time I first saw her she was unable to live with her family in Boston, because the stir of life in the city was unendurable. She complained chiefly of frequent attacks of faintness with a sinking sensation over the precordia. While I was obtaining the clinical history she became much agitated, and began to breathe deeply and heavily. Her face became flushed, and she complained that the room was very hot, although it was really uncomfortably cool. She begged to be led to an open window, and was fearful that she would faint.

I suggested that mild hydropathic treatments might be of value. She consented to try them, although she stated that in the past she had been unable to take even sun-baths. Very gentle procedures were employed. At first *Treibschümpen*, later douches. It was found necessary to fan her constantly while in the electric light cabinet. Her condition improved greatly and she is now able to live in town, and states that she feels like another woman. She still has very little nervous capital and continues to take treatments.

enlarged middle turbinate, polypi, etc., and the irrigation of the sinus through the naso-frontal canal.

Rhinologists differ as to the results obtained by this procedure. Turner¹ is of the opinion that the number of cases cured must be very small, while Hajek² takes a more favorable view, which is shown by his report of the intranasal treatment of twenty-seven cases. Out of this number nine were cured, eleven had a slight muco-purulent secretion remaining, while only seven received no improvement in physical signs, although the headaches were stopped in all but three.

Ingals³ has recently advocated a method of enlarging and maintaining the patency of the naso-frontal canal, which adds to the possibilities of the intranasal treatment and deserves careful trial.

Schaffer's⁴ method of perforating the floor of the sinus between the middle turbinate and septum should never be undertaken.

The external ways of reaching the frontal sinus are numerous and can be most easily reviewed in a tabulated form. The first group includes those operations that permanently remove a part or the whole of the sinus wall.

1. Removal of the anterior wall.
 - (a) Entire anterior wall. Kuntz.⁵
 - (b) Part or the whole of the anterior wall with enlargement of the naso-frontal canal. Ogston,⁶ Luc,⁷ Nelinger, Praun,⁸ Ropke,⁹ Croakley.¹⁰
2. Removal of the inferior wall. Jansen.¹¹
3. Removal of the anterior and inferior wall. Richards.¹²
4. Removal of the anterior and inferior wall. Riedel.¹³
5. Removal of the anterior wall of the sinus and the frontal process of the superior maxilla. Hartmann.¹⁴
6. Removal of the anterior and inferior wall of the sinus, leaving a bridge, and the frontal process of the superior maxilla. Killian.¹⁵

The second group includes the operations that temporarily resect the anterior and inferior walls. Osteoplastic methods of Brieger,¹⁶ Czerny,¹⁷ Winekler,¹⁸ Barth,¹⁹ Hajek,² Lothrop.²¹

The object of these operations is to leave the sinus intact or to obliterate it.

In a case of chronic purulent frontal sinusitis, in which intranasal treatment has failed to give relief, which of our present operative procedures is the best to permanently relieve the patient of his symptoms, with the least danger, deformity and time? Such an operation should, first of all, freely expose the sinus so that all parts can be examined and diseased areas completely removed.

2. It should include the removal of the anterior ethmoid cells, as these cells are nearly always associatedly diseased. Zuckerkandl²² states that he has never seen a case on the post-mortem table with disease of the frontal sinus, which did not show involvement of the ethmoid cells.

3. It should provide a large opening for drainage, preferably into the nasal cavity, after nature's example. This opening as Zarnko²³ says, "should not be like a narrow neck bottle but like a wide open bay."

DESCRIPTION OF KILLIAN'S FRONTAL SINUS OPERATION.

BY E. E. FOSTER, M.D., NEW BEDFORD, MASS.

THE treatment of chronic frontal sinusitis may be considered under two heads, the intranasal, or the so-called conservative method, and the extranasal, or the radical procedure. The former comprises the removal of all irregularities causing an obstruction to free drainage from the frontal sinus: such as a deviated septum, an

4. It should be as free as possible from danger to life, produce little disfigurement and have a short after-treatment.

None of the operations presented will cover these demands so completely as Professor Killian's. His operation includes the best features of the other operations and in my opinion possesses the merits of as near a universal frontal sinus operation as has yet been conceived. It should be undertaken, however, only by persons possessing a thorough knowledge of the anatomy of this region, and with surgical ability.

The principals of the operation are the same as described by Killian in the *Archiv für Laryngologie*.¹⁵ As a result, however, of further experience he has been able to add much of value in the way of technique, which has improved, to quite an extent, the results of the operation, as his later cases show. These improvements in technique were reported by him at a meeting of the Vereins Süddeutscher Laryngologen in Heidelberg, June, 1904.²⁴ In our literature there are several brief outlines of this operation (Derby,²⁵ Freudenthal,²⁶ Canfield,²⁷ Harris²⁸), but each is based upon the original description and does not include the recent improvements, especially the resection of the floor of the sinus from below and the details for resecting the frontal process and diseased cells.

Zarniko's²³ description, which is the best that I have found in the German literature, is not wholly in accord with Killian's lately reported improvements.

I have seen the so-called Killian operation performed both here and in Europe, and I know the results would have been better in most instances had Killian's method been more thoroughly understood. It is with this in mind that I have prepared the following brief account of the operation as I have seen it done by both Professor Killian and his assistant, Dozent von Eicken.

Up to June, 1904, they had operated upon 50 patients.

Killian considers as indications for his operation the following conditions:

1. When other operations have failed.
2. When there are indications of necrosis, as a fistula or abscess.
3. When there are symptoms of intracranial complications.
4. When in a case of chronic purulent frontal sinusitis pain and fever appear with a foul smelling discharge.
5. When there is headache, particularly when associated with discomfort in the region of the eye, which is not relieved by intranasal treatment.
6. When, in spite of oft repeated irrigations of the sinus, the discharge remains foul.
7. When the inflammation in the frontal sinus and anterior ethmoid cells produces recurring groups of polypi.
8. When a simple purulent discharge is not relieved by careful intranasal treatment, and the patient desires permanent relief by a radical procedure.

If possible, the outlines of the sinus should be determined by skiagraphy before any surgical interference is undertaken. In the hands of a skillful operator, skiagraphs can be made showing a clear outline of the sinus.

Scheier²⁹ states that skiagraphy will determine the presence or absence of the frontal sinus, the antero-posterior diameter, the height and the thickness of the anterior wall. Winckler¹⁹ even claims that he can determine the thickness of the floor and relations of the ethmoid cells.

A quarter of an hour before beginning the operation the patient is given subcutaneously $\frac{1}{4}$ grain (0.01) of morphine. Formerly the affected sinuses were then washed out and the nasal tampons put in place, but of late this is omitted, so as not to unnecessarily excite the patient. The patient is placed upon an operating table with the body raised. An anesthetic is administered. Killian uses chloroform. During, or immediately after, the anesthetization, the nasal cavity of the affected side is filled with four tampons made of cotton rolled into the shape of a small Perfectos cigar, with a thread fastened about the middle. The first one is firmly placed along the floor of the nose, between the inferior turbinate and septum; the second in the middle meatus; the third fills the olfactory cleft, and the last (which is an important one) is placed firmly in the forward part of the nose, beneath the bridge and between the frontal process of the maxillary bone and septum. This last tampon supports the mucous membrane covering the frontal process, thus preventing hemorrhage and injury during the resection of that bone. The mucous membrane thus saved forms the largest part of a flap to be described later. The first and second tampons are placed far back so as to completely close the choana. Killian never uses a post-nasal plug.

The field of operation is prepared in the usual way with soft-soap, alcohol and corrosive. Extra care should be used in cleaning the eyebrow as it is not shaved. In some of Killian's early cases, where the eyebrow had been shaved, the hairs grew very long or did not grow at all, producing in either case an unsightly appearance. He has experienced no infection as a result of leaving the eyebrow. The eye on the affected side is protected with a few layers of moist gauze, and the part of the head and body not included in the field of operation, should be carefully protected with sterile towels and sheets. Two assistants, an anesthetizer and a nurse are needed.

The surgeon stands on the side of the table corresponding to the affected sinus, facing the head of the patient. The first assistant and anesthetizer stand on the other side. The second assistant stands on an elevated platform at the head of the table. He steadies and moves the patient's head from time to time as the surgeon may wish. An electric head lamp should be at hand. The Kirstein lamp is the best. Reflected light can, of course, be used. This operation can be performed with chisels, bone forceps and the usual instruments of the ordinary surgical kit, but it is made much easier and more rapid by

using Killian's straight and curved V-shaped chisels (Fig. 1) and eye protector (Fig. 2), Hartmann's or Gründwald's cutting forceps and Lomhard's or Jansen's bone forceps. A medium-sized straight sound should be included in the list of instruments.

The initial preparations being completed, the actual operation is commenced. Killian makes three distinct incisions: The first through the

FIG. 1. Killian's straight and curved V-shaped chisels.

skin, the second through the subcutaneous tissues to the periosteum, and the third through the periosteum. The neatness and care used in making the first and third incisions has much to do with the cosmetic result. The first one begins at

FIG. 2. Killian's protector.

the temporal end of the eyebrow, extends inward through its middle to the nasal end, where it passes downward in a graceful curve along the root and side of the nose to and a little below the base of the nasal bone (Fig. 3). During the

operation the two edges of the wound are considerably stretched and difficult to accurately oppose when ready to suture. A bad approximation would produce more or less disfiguration. Killian overcomes this by making, at regular intervals, four or five short superficial incisions at right angles to the long one just described. (Fig. 3.) While cutting through the subcutaneous tissues above the eye, it is advisable to protect it and the supra-orbital margin, and to steady the tissues, by carrying a finger of the left hand beneath the supra-orbital margin with the progression of the knife. The hemorrhage is arrested with pressure and light clamps, which are left hanging. If the gauze pad protecting the eye has been soiled or pushed out of its place, which is usually the case during the above procedure, it must be replaced so that the clamps

FIG. 3. The long and transverse skin incisions.

and instruments will not injure the eye. The edges of the wound are now slightly separated with retractors and the incisions made through the periosteum. The first begins at the temporal end of the original incision, extends inward 6 to 8 mm. above and parallel to the supra-orbital margin, to the upper end of the nasal bones.

(Fig. 4.) The second begins one quarter of an inch internal to the supra-orbital notch, extends inward on the orbital margin until it intersects the nasal portion of the skin incision, which it follows to its lower end. (Fig. 4.) Formerly, the first part of this incision was made only 5 to 6 mm. above the supra-orbital margin, and the groove was marked off a little way above, leaving a part of the supra-orbital bridge uncovered with periosteum. Now the bridge is completely covered, as will be explained later. The periosteum covering the anterior wall of the frontal sinus is elevated and retracted. If the outlines of the frontal sinus have been determined by skilfully the groove forming the upper margin of the supra-orbital foramen can be made, otherwise a groove must be made into the sinus for the purpose of finding out, with a probe, its size and shape. The

opening can be made either above the supra-orbital bridge, to be formed, or just below it, at the root of the nasal bone. (Fig. 4.) The latter is the safer place. According to Mosher³⁰ the sinus in one third of the cases is just within the rim of the

FIG. 4.—The heavy lines represent the first and second periosteal incisions. The lighter curved line outlines the area of bone to be removed for the purpose of probing the sinus.

orbit at its superior internal angle. The opening should be made through the bone with a chisel, exposing but not perforating the underlying mucous membrane. A probe can then be passed between the bone and the mucous membrane outward, upward and inward, giving an approximate size of the anterior wall of the sinus. The temporal end of the sinus is marked off and a groove made from this point, extending inward nearly to the median line close to or a little below the edge of the periosteum covering the supra-orbital ridge, that is: 5 to 7 mm. above the supra-orbital margin, the object being to leave the bridge completely covered with periosteum. (Fig. 5.) This groove can be made quicker and better with a straight V-shaped chisel (Killian) although an ordinary flat chisel can be used. The lower surface of this groove forms the upper edge of the supra-orbital bridge, consequently it should be smoothly and evenly made. After the groove has been made deep enough to enter the sinus, all of the anterior wall of the sinus lying above can be removed with Lombard's, Jansen's or an ordinary bone forceps and chisel. Care should be used not to break the bridge during the resection. When the anterior wall has been completely removed, the mucous membrane and any partial bony septa must be carefully and completely erased, special attention being given to nooks, corners and the posterior surface of the supra-orbital bridge. All sharp corners, grooves or depressions must be obliterated by beveling off the surrounding elevated bone, thus leaving a smooth surface where pus cannot be retained.

This completes the work above the bridge. The sinus is loosely filled with gauze and the retracted tissues allowed to assume their normal position.

Our attention is now given to the resection of the frontal process of the superior maxillary bone. The periosteum is elevated and retracted from the nasal bone, frontal process, lacrymal groove and orbital portion of the frontal bone, toward, but not to, the supra-orbital notch. Killian's small-sized, bent, V-shaped chisel is placed at the lower end of the suture, between the nasal bone and the frontal process of the maxillary bone, and driven upward with a mallet along this suture, forming a groove as it goes. This groove is extended from the upper end of the suture into the frontal bone, toward, but not to, a point midway between the supra-orbital notch and the attachment of the trochlea, thus forming the lower edge of the supra-orbital bridge. The chisel is again placed at the lower end of the suture, as above, but this time it is driven at right angles to the suture, that is, through the frontal process toward the lacrymal bone, care being used not to injure the lacrymal sac (*vid. Collin's case*³¹). This groove prevents the downward breaking of the frontal process during its resection. (Fig. 5.) The resection can be best accomplished by starting at the lowest portion of the frontal process to be removed. This is just above the last made groove. Here the bone is thinnest and can be easily perforated without injuring the underlying mucous membrane, which must be

FIG. 5.—Grooves made with the V-shaped chisels to form the upper surface of the bridge and to outline the portion of the frontal process of the maxillary bone to be removed.

preserved for use as a flap. After a small opening through the bone has been made, bone forceps will very quickly remove the largest part of the process, but at the upper end a chisel may be needed. The resection is extended a little way above the frontal process including a small part of the frontal bone, which is a part of the sinus floor.

The removal of this bony area gives us free access to the floor of the sinus and the nasal cavity. The periosteum is now elevated from the remaining lachrymal bone and groove, from the orbital portion of the ethmoid bone posteriorly to the anterior ethmoidal vessels, and from the orbital portion of the frontal bone lying inward and downward to the trochlea attachment and supra-orbital notch. In other words, the limits for elevation and resection are: The lower part of the lachrymal groove below; the anterior ethmoidal vessels behind; and the trochlea attachment and supra-orbital notch above. The elevation is very easily done with Killian's protector. The orbital tissues are then retracted outward with the protector, and held in place by the first assistant. This gives a good view of the operative field, and makes a space in which to remove the remaining sinus floor, part of the ethmoid plate and lachrymal bone, the erosion of as many of the ethmoid cells as is found necessary, and even the opening of the sphenoid cell, if it is diseased. There is no way of so accurately and safely operating upon the ethmoid and sphenoid cells as through an opening made by the resection of the frontal process of the maxillary bone. The tampon in the forward part of the nose and the one in the olfactory cleft are now removed, the above mentioned bones resected, and the diseased cells obliterated. This is best accomplished with Gröndwald's, Hartmann's, or a similar cutting forceps and curettes, under the guidance of good artificial light. Any part of the frontal sinus floor or wall that cannot be reached from below, can be from above. Formerly Killian removed the whole of the floor of the sinus from above, but at the present time does not, except for reasons just stated.

In doing this resection the limitations must be kept in mind, that is, the lower part of the lachrymal groove below, the anterior ethmoidal vessels behind, and the trochlea attachment and supra-orbital notch above. When it is necessary to destroy ethmoidal cells posterior to the anterior ethmoidal vessels, it must be done internal to the remaining orbital plate of the ethmoid bone. After the above resection has been completed, we have a large opening from the frontal sinus into the nose, with the supra-orbital bridge in front. (Fig. 6.) The surface of the whole bony field must be made perfectly smooth. The operation is completed by making a flap of the uninjured mucous membrane that covered the resected part of the frontal process of the maxillary bone, and any adjoining healthy mucous membrane. This is done by perforating, with a sharp-pointed knife, the mucous membrane at the lower edge of the nasal bone, and by means of a probe-pointed knife the incision is continued upward along the edge of the nasal bone to within 4 cm. of the cribriform plate, where it extends backward as far as there is good mucous membrane to be used, then downward. This flap is pushed outward against the adjoining orbital tissues. If the middle turbinate has not been removed, and its mucous membrane is not degenerated, an extra

flap can be obtained by removing the forward part of the bony structure of the turbinate. This can be easily done by steadying the turbinate with a medium-sized sound in the olfactory cleft, while the bone is being removed with curette or forceps, passed through the opening made by removal of the frontal process. If the nasal mucous membrane is degenerated, the formation of a flap may be omitted.

The wound is cleaned with normal salt solution and dried. The whole area should be carefully examined for projections, nooks and corners that could in any way prevent perfect drainage. Iodoform is blown into the wound. The two remaining tampons in the nasal cavity are removed. A narrow strip of iodoform gauze is loosely placed in the region of the ethmoid cells, an end of which hangs out of the nasal orifice. In placing this

FIG. 6

gauze see that the mucous flap is in its proper position. The remaining part of the nasal cavity is filled with cotton tampons. The tampons and gauze are removed on the second day, not to be renewed, as the opening from sinus into nose is so large that all secretion will easily flow out.

In cases where the septum is deviated to the affected side and would make the opening from the sinus into the nose too narrow for good drainage, it should be straightened by the submucous resection method before undertaking the sinus operation. If Killian's¹² submucous method is used the delay will be only for three or four days. The skin in the field of operation is elevated and the wound edges are immediately sewed together with aluminum-bronze wire, when none of the following contra-indications exist. Acute process, whether it be primary or an exacerbation of a previous attack, when there is a question of an intracranial suppuration, when the pus is foetid, there exists a decided necrotic process. In all of these conditions the secretion is violent and

ought not to be inclosed in the sutured wound. The wound can be, however, safely sutured on the second or third day. Killian has immediately sutured twenty-four cases out of thirty-one, or about 80%. Great care must be used in accurately approximating the two wound surfaces. This, however, is easily done if the short superficial incisions were made at the beginning of the operation. (Fig. 3.) When the wound is not united at the end of the operation, the two surfaces are slightly separated by a gauze drain. Before applying the dressing a drop of a 1% solution of atropin is instilled into the eye. The eye is covered loosely with gauze and a good-sized dressing of moist boric acid gauze placed over all. The patient is put in bed upon the sound side, and made to lie in this position most of the time for a few days. He is forbidden to blow his nose, and told to draw into the throat all wound and nose secretion, which can be expectorated. The dressing is removed every day. The nasal tampons and gauze packing are removed on the second day. On the fourth or fifth day the sutures can be removed. A day or so later the eye is left uncovered when applying the dressing, and shortly the dressing is omitted entirely. This, of course, applies to those cases where primary union takes place. The nasal cavity is not flushed out, nor is there much intranasal treatment. At the end of the third or fourth week the wound cavity, lying above the mucous covered nasal cavity, is painted with a 2% solution of nitrate of silver, care being used not to touch the mucous membrane of the nasal cavity.

Luc,²³ who has adopted this method of operating on the frontal sinus, pays considerable attention to the after-treatment. He removes the crusts daily and carries upward into the cavity a tampon of wool soaked in peroxide of hydrogen, or a weak solution of iodine. The amount of depression above the supra-orbital bridge depends upon the size and depth of the sinus. Fortunately, however, depressions of almost any size can be filled in with the proper use of paraffin. When the maxillary sinus is associatedly diseased, it should be first operated upon, and after tightly packing, the frontal sinus attended to. As stated above, all the diseased ethmoidal cells and sphenoid cell can be most easily removed through the opening made by the removal of the frontal process of the superior maxillary bone. Killian has operated seven times upon all the accessory sinuses of one side with good results. If both sides are diseased, only one side at a time should be attended to, the other side being left until the operated side is healed. Killian says that patients willingly return for the second operation being so well pleased with the results of the first.

During my stay in Freiburg I saw this operation performed eight times and had the opportunity to observe four other patients on whom the operation had recently been done. The relief of symptoms was perfectly satisfactory. The disfigurement varied in accordance with the size and shape of the sinus, but after the use of paraffin

the cosmetic results were all that could be desired. There was no deformity below the bridge. The convalescence was of short duration, with very little after-treatment. Iritis did not occur, neither did I see permanent diplopia.

In a series of eighty cases, published and unpublished, that I have been able to collect, only two deaths occurred, making a mortality of only 2½%. The cases collected by Turner¹ show 87% of cures for the Killian operation as against 58% for the Ogston-Luc. I am confident that this percentage of cures as a result of the Killian operation will be markedly increased and the mortality decreased after the operation is better understood and carried out.

In December, 1904, I assisted Dr. Owen Smith of Portland, Me., in performing this operation on a woman seventy-six years of age, who had been suffering for a long time with chronic purulent frontal sinusitis.

The accompanying photograph (Fig. 7) was made of this patient at the time of her discharge from the hospital, three weeks after the operation.

FIG. 7.—Three weeks after a Killian operation on the left frontal sinus.

The eyebrow was shaved, as we were not obliged to consider personal appearance, so the supra-orbital scar is more noticeable than it would otherwise have been. The convalescence was free from complications. Practically no pus appeared after the removal of the tampons and ethmoidal packing. No after-treatment.

A STUDY OF THE LARYNX IN TABES.*

BY D. CROSBY GREENE, JR., M.D., BOSTON.

THE subject of laryngeal disturbances in tabes has been investigated by many observers. The most valuable work is an elaborate monograph on the subject published in 1903 by H. Dorendorf, of Berlin, in which there is a complete résumé of the literature to date, and a detailed report and study of laryngeal manifestations found in the course of the examination of 245 cases of tabes in Gerhardt's clinic in Berlin. I have referred to this work frequently.

My purpose here is to report the result of recent examinations made at the Massachusetts General Hospital, the Massachusetts State Hospital at Tewksbury, and at the Long Island Hospital in sixty cases of tabes.

These were observed with reference:

- (1) To the proportionate number affected with paralytic and other disturbances of the larynx.
- (2) To the nature of such disturbances, and.
- (3) To the period of their occurrence in the course of the disease.

(1) Out of the 60 cases examined, 9, or 15, presented laryngeal complications. 6, or 10, showed undoubted paralysis of one or both vocal cords; 7, or 12%, were affected with laryngeal crises, 3 of these without evident paralysis of either cord; and one presented a peculiar movement of the cord in moving from the median to the lateral position. Dorendorf found paralysis in 12, or 5% in 3% of his cases, while 1% showed the peculiar movement of the cords which has been called ataxic, a much larger proportion than I observed.

(2) In regard to the nature of these disturbances, the only form of paralysis which I observed was abductor paralysis. Of the 6 cases 5 were unilateral and one was bilateral. These were further divided into 3 with partial and 2 with complete abductor paralysis, that is to say, in the former there was marked limitation of outward excursion of the cord and in the latter there was absolute fixation of the cord in the median position.

* Read at a meeting of the New England Otology and Laryngology Society, Nov. 17, 1905.

In partial paralysis the cord at rest is approximately in the cadaveric position. It moves to the median position in phonation, but does not move outward beyond the cadaveric position in respiration. It is not warrantable to make the diagnosis in this stage without repeated examinations at intervals on account of the variation in the excursion of the vocal cords which may be noted in normal individuals. In this connection I will mention one source of error in making the diagnosis of partial paralysis, pointed out to me by Dr. Coolidge, which lies in an asymmetrical position of the larynx not infrequently met with. The larynx being tilted to one side or the other there may be a difference in the degree of movements of the two cords as seen by the laryngoscope which is apparent rather than real.

In complete abductor paralysis there is no difficulty in diagnosis. The cord remains constantly in the median line. At the same time the arytenoid on the affected side is tilted forward depressing the processus vocalis so that the cord appears shortened and at a slightly lower plane than its fellow. There is also some bowing of the free edge of the cord. The change from the condition of partial to that of complete paralysis has been observed by Dorendorf in a few cases.

It is a remarkable fact that in this disease the paralysis should limit itself in the great majority of cases to the posterior crico-arytenoid muscle while all the other intrinsic muscles which are supplied by the recurrent nerve, with the exception of the thyroarytenoid internus are apparently unaffected. Grabow showed conclusively in a number of cases which were at first said that there was a degeneration in the motor fibers of the vagus which supply the recurrent laryngeal nerve, but he found that in a few test not only those fibers which supply the posterior crico-arytenoid, but also those supplying the other intrinsic muscles of the larynx. Recently he has further shown by actually counting the number of fibers which go to the different groups of laryngeal muscles that the crico-arytenoid is supplied with a comparatively small number of fibers, and that the other groups are supplied with a much larger number.

The explanation of this apparent restriction of the paralysis to the abductor muscle seems rather to be that we are concerned with a slowly progressive degeneration of the other intrinsic muscles of the larynx. This is in accordance with the well known fact that the posterior crico-arytenoid is the last to be affected in the degenerative changes in the motor fibers of the vagus in tabes.

The explanation of the fact that the majority of the cases are unilateral and that the majority of the unilateral cases are on the right side is not clear. When the paralysis is bilateral it is usually of the crico-arytenoid internus and thyroarytenoid internus.

A further point of interest is that in the majority of cases the paralysis is unilateral and that the majority of the unilateral cases are on the right side.

Further study of the larynx in tabes is necessary in order to determine the exact nature of the changes in the motor fibers of the vagus which supply the larynx.

in four of my cases, and without paralysis in three cases. These crises are characterized by pain or a sense of irritation in the larynx followed by cough, dyspnea and loud inspiratory stridor. In a mild case the attack closely simulates whooping cough. It begins with a succession of short coughs followed by an inspiratory whoop. Then comes another succession of coughs followed by another whoop, each succeeding whoop being a little severer than the last up to a certain point when the attack begins to subside. There is no distress manifest, and the attack lasts only a few minutes. In severe cases, on the other hand, the attacks are most alarming. The breathing becomes noticeably difficult, the inspiratory stridor is loud and prolonged. The face becomes cyanotic, and in the worst cases the patients fall to the ground, lose consciousness, the breathing stops and epileptiform twitchings occur. Death may occur, but in the great majority of cases the attacks end spontaneously. One of my cases with bilateral abductor paralysis, who had for two or three years laryngeal crises of the most violent type at frequent intervals, almost every day, now has them only once in a few weeks. The attacks have greatly diminished in severity and he has now very little dyspnea. This is probably due to the fact that the adductor muscles are now weakened to such an extent that they can no longer produce strong spasm of the glottis.

I have mentioned the appearance in one of my cases of a jerky movement of the cords in moving from the median position. After phonation the outward excursion of the cord was interrupted, the cord remaining stationary for a moment on its way to the position of abduction. This is the so-called ataxia of the cords reported by Krause, Semon and others. The phenomenon is a comparatively rare one, and its etiological relationship to tabes is not established.

Disturbances of sensibility in the larynx, hyperesthesia and anesthesia have also been reported by other observers, but I did not find any case in which the disturbance seemed marked enough to justify one in classing it outside of normal limits.

(3) With reference to the stage of the disease in which laryngeal manifestations appear, I found that laryngeal crises, when present, occurred among the earliest symptoms in all of my cases. In two the crises led to examination of the larynx and subsequent detection of the disease of the nervous system.

Unilateral abductor paralysis does not of itself necessarily interfere with phonation or respiration. It may, therefore, exist for a long time without being discovered. Lockard reported four cases of abductor paralysis in which other symptoms of tabes were preceded by some months. It is obviously impossible to say in what stage of the disease paralysis of the cords occurs in the majority of cases, but we are justified in inferring that it probably occurs early.

I will close with a brief account of the two cases I saw in which examination of the larynx led to the diagnosis of tabes.

CASE I. April 22, 1905. C. E. C., a colored laborer came to the Throat Department of the Massachusetts General Hospital for treatment of his throat. He stated that his present trouble had begun ten days previously when he was seized in the evening by a violent spasm of coughing associated with a painful strangling sensation in his throat. He could hardly breathe. One or two similar attacks had occurred almost every day since that time. He admitted having acquired syphilis ten or twelve years before, but thought he had long been cured of that and was in good health at the time of his first attack of coughing. He now complained not only of these attacks but of loss of strength and general lassitude.

On laryngeal examination the left vocal cord was seen to remain fixed in the median line during both phonation and respiration. The left arytenoid was tilted forward and the cord was shortened in appearance. The free border was concave. The right cord presented the normal degree of excursion and during phonation met its fellow in the median line, the resulting vocal sound being somewhat roughened.

The patient was then referred to the Nerve Department where he was examined by Dr. Baldwin, who made the diagnosis of tabes on absence of the patella and Achilles reflexes and the characteristic Argyll-Robertson pupil.

This case was, then, one of typical unilateral abductor paralysis in tabes, in which the laryngeal examination gave the first intimation of the essential lesion of the nervous system.

CASE II. The second case, H. B. R., was a man forty-five years of age, who first came under my observation in June, 1904, in the Throat Department of the Massachusetts General Hospital. He had been troubled for several months with a spasmodic cough which he attributed to irritation in his throat.

Although he gave no history of venereal disease, his throat presented numerous evidences of an old ulcerative process which had healed leaving several scars in his fauces and a small perforation of the right anterior pillar. The laryngeal examination was rendered most difficult by the anatomical deformity of the upper part of the larynx, especially the epiglottis. The latter was narrow, curved longitudinally and drawn backward by cicatricial contraction of the aryepiglottic folds. The entire ventricle was constricted, but not sufficiently to offer obstruction to respiration, which was usually free. I was unable to see more than the posterior ends of the vocal cords, but this was sufficient to show that there was a limitation in the outward excursion of the right vocal cord. This observation was confirmed by two subsequent examinations at intervals. I at first attributed the limitation in movement to the cicatricial condition noted. At his second visit, however, the manipulation for making the laryngoscopic examination apparently started a slight attack of coughing which, instead of desisting after I had stopped the examination, increased. A succession of short coughs was followed by an inspiratory whoop which was in turn followed by more coughs and a louder whoop, and so on for several minutes, and then the attack gradually subsided. At the height of this attack the patient was cyanotic and was plainly distressed for breath. He informed me that it was for just such attacks which occurred daily and sometimes several times a day, that he had come for treatment.

This patient was also referred for examination to the Nerve Department where the diagnosis of incipient tabes was made.

The practical conclusion to be drawn from this study from a laryngologist's standpoint is that tubes as an etiological factor, either of vocal cord paralysis or spasmodic laryngeal cough, should never be overlooked.

I am indebted to the staff of the Nerve Department of the Massachusetts General Hospital for their courtesy in allowing me free rein in the examination of their cases of tubes.

A CONTRIBUTION TO THE ETIOLOGY OF "LATERAL CURVATURE" OF THE SPINE.

BY MAX BÖHM, M.D., BOSTON,
Massachusetts General Hospital.

I wish to present three cases of "lateral curvature" of the spine, which I have had a chance to examine by means of the x-ray during the last week, and which show conditions interesting for the anatomist, biologist and especially the orthopedist. The cases are three girls, J., S., and T., sixteen, fifteen and twenty-three years of age; two of them attend school, one does housework.

Their history shows so few characteristic features, that it does not seem worth while to give it here *in extenso*. I only need to mention that there is no hereditary history of spinal curvature, no history of rickets in childhood.

The present affection came on extremely slowly, in the oldest case five or six years ago, in the two other cases two or three years ago without any symptoms to speak of. The deformity was not noticed first by the patients themselves, but by the aunt or the dress-maker.

The examination shows us three girls of apparently good health and constitution, with no deformities in the extremities, no signs of past or present rickets, no asymmetrical shortening of legs.

The spine deformity, represented and clearly seen in the following records shows in case J. a typical left lumbar with compensation mostly in the cervical part, the rotation on the convex side of the curve. In both other cases S. and T. there is the typical S-curve, more marked in T. than in S.; the rotation is present in lumbar and dorsal region on the convex side, and is still more marked in bending over. There is practically no limitation of the spinal motions. Thus the cases represent what is known to every medical man as juvenile or habitual scoliosis (primarily lumbar).

In each case a careful x-ray was taken. This was done under my supervision with the patient lying flat on the back, as the compression-extractor was used the spine had to be taken in three sections, one overlapping the other. A print of each one was made afterwards and the prints were put together to a full spine. (Röntgen was used only in case J.)

The x-rays show, as to the curvature condition

corresponding to the clinical picture. Lateral deviation and distortion in the whole spine are clearly seen.

The most surprising conditions are offered by the lowest lumbar vertebra. The explanation of these conditions is very difficult for many reasons. In the first place the region has practically never been studied by the radiologist; it offers, furthermore, many anatomical difficulties, for instance, prominences in antero-posterior direction, overlapping each other; a lateral view can hardly be taken, finally as to our special cases here, the conditions seem to me entirely new. For all these reasons it seems to me a very bold undertaking to try to explain the conditions entirely and I am sure my description will be an incomplete one. But it is merely the aim of this paper to call the attention of the orthopedic surgeons and radiologists to these conditions for criticism and further study.

As far as I am able to explain the x-ray pictures, the lumbosacral region gives evidence of an anatomical and apparently congenital malformation in the sense of an incomplete development of a sixth lumbar vertebra with more or less fusion to the fifth lumbar vertebra and to the sacrum. Further studies must explain the details.

That these conditions exist and are already known to the anatomist is shown by the wonderful collection of congenital abnormalities of the spine in the anatomical department of the Harvard medical school, probably the foremost collection of this kind in the world. Professor Dwight had the great kindness to demonstrate this collection to me and gave me the permission to use his specimens for further study and research. I am very much indebted to him.

The very justifiable question will come up: "Granted that my x-ray explanations are right and that the conditions represent congenital malformations of some form in the above-mentioned region, are they only incidental or do they really represent the cause of the spine curvatures in our three cases?" In answer to this question has to be said: The top of the sacrum and the fifth lumbar vertebra are the foundation of the human spine and only as long as this base is normal, that is symmetrical, the symmetrical development of our spine is possible. Consequently, if, for instance, a supernumerary lumbar vertebra between the fifth and the sacrum should occur, the symmetrical development of the spine would not be disturbed, as long as this intercalated vertebra is in itself symmetrical. That is what we see in many of Professor Dwight's specimens. So am I sure there are many individuals who have a straight spine in spite of congenital abnormalities in the lumbar or sacral region. On the other hand the theoretical supposition is justifiable that many of these abnormalities will take place in an asymmetrical way and will disturb the symmetry of the foundation of the spine and, therefore, produce spinal curvatures, partly directly in a mechanical way, partly indirectly by compelling the body to compensate it. There are already anatomical proofs that spinal deformities

ities with the typical lateral and rotatory components can result from the above-mentioned conditions. Breuss and Kolisko¹ publish in their book on the pathology of the pelvis an anatomical specimen, in which the asymmetry of a fifth lumbar vertebra with two arches and two transverse processes produced a spinal curvature, a specimen almost exactly corresponding to our case S.

At this point I wish to warn against comparing spinal curvatures seen in museum specimens and those seen by the x-ray. For anatomical specimens are not subject to muscular action and show the curves only as far as they are due to structural changes; they have furthermore gone through an artificial drying process. On the other hand, the x-ray shows us curvatures as they exist in living persons, due to structural changes as well as to muscular conditions. Although the above question cannot be definitely settled by my three cases, I believe that in these cases the malformation of the lumbó-sacral region is the exclusive and sufficient cause of the curves, and that these three cases represent true congenital deformities.

Few words may be allowed from a developmental point of view. In the development of the species man out from lower species "the ilium travels upward on the spine" (Dwight), a loss of vertebrae takes place gradually. From this standpoint human individuals which have six or five and one-half lumbar vertebrae would represent a lower type of human beings. According to this theory our patients would belong to this class and their deformities are of atavistic character.

The chief places of the spine where this loss or transformation of vertebrae takes place are, according to Rosenberg, the lower lumbar and the lower dorsal region. These places are also known as the primary places for juvenile spine deformities. Further examinations would have to show whether a connection exists between both these parts.

In conclusion I want to mention, in order to prevent any misunderstanding, that I do not claim that the above-mentioned congenital conditions, shown in the x-rays, represent the *exclusive* cause of all "lateral curvatures," not even of the primary lumbar curve. On the other hand, it does not seem to me that these conditions represent curiosities; but the fact that I found inside of one week these three cases seems to me very suggestive, that this cause of lateral curvature is not very uncommon.

Many other interesting points, for instance, the possible treatment, will be made the subject of an extensive report, following this preliminary one.

My best thanks are due to Drs. Goldthwait and Osgood for permission to use the cases.

It is stated that the *Maine Journal of Medicine and Science*, formerly the official organ of the Maine Academy of Medicine and Science, has discontinued publication.

Clinical Department.

CONTUSIONS OF THE ABDOMEN.

BY JOSHUA C. HUBBARD, M.D.,

Third Assistant Visiting Surgeon, Boston City Hospital; Physician to Out-Patients, Boston Lying-In Hospital.

WITHIN a comparatively short time I have had the opportunity of seeing several patients whose condition has impressed me with the importance of the most careful observation in cases of contusion of the abdomen, and I wish now to report them, not to bring out anything new in the way of diagnosis or treatment, but simply to emphasize the great difference both in severity and kind of lesion which may be produced by blows upon the abdomen.

Although it is a well known fact it will bear repeating, that in such cases the extent of the lesion produced bears no relation to the severity of the trauma. Of by far more importance is the condition of the abdominal wall, whether relaxed or contracted, the state of the intestines, distended or empty, and the length of time elapsed since eating or emptying the bladder. No increasing scale of lesions can be made for each increase in the amount of force in the trauma. Blows of but slight force may produce the gravest intra-abdominal injuries in some patients, while others escape without any serious damage from the most severe accidents.

One of the most difficult problems a surgeon has to face is often met in these cases of abdominal trauma. To postpone necessary interference till the diagnosis is certain from evidences of peritonitis or hemorrhage is to be most strongly condemned for by so doing in many cases the life of the patient is simply thrown away. The prognosis depends, in the operative cases, one could almost say, entirely on the length of time elapsed from the receipt of the injury to the operation. For this reason all doubtful cases should be treated until diagnosed with great care even to the minutest detail, for, if the given case prove later operative, every moment spent in reaching a decision affects the prognosis. In most of the operative cases the exact diagnosis of the nature of the intra-abdominal lesion is not made till the operation, and in many of them it would be wrong to wait long enough to make such a diagnosis. The arguments for and against operation should be considered and that is all. When once the decision has been made that an operation is necessary, any time spent in trying to differentiate hemorrhage from rupture of the intestine, for instance, makes the prognosis just so much the worse. The practical differential diagnosis and the one on which the prognosis depends must then be made between contusion of the abdominal wall and injury to the abdominal contents, in other words, whether a given case demands operation or not. I do not wish it understood that I belittle the attempt to diagnose the exact nature of the intra-abdominal injury for that is not so. I simply make this exact diagnosis secondary to the general diagnosis of intra-abdominal trauma.

CASE T.

CASE T.

CASE T.

CASE T. Striking asymmetry of last lumbar vertebra; probably additional presacral vertebra, showing left lumbar, right sacral character. On the left fusion to sacrum (?).

A working diagnosis of whether to operate or not cannot be made in a certain number of cases immediately. A given case may have to be observed for perhaps a half hour, perhaps two or three hours, or longer, and the changes in the physical condition noted by the surgeon on whom the responsibility of a decision is to rest. I repeat to emphasize that the one who is to operate must have the opportunity of seeing the patient early, and following the changes himself. No amount of description can ever take the place of a few passes of the hand over the abdomen.

As a last resort to aid in making a diagnosis in those cases whose condition is progressively becoming worse the abdomen should be explored. There is no question about such an exploratory laparotomy being justifiable. A surgeon failing to do so in the cases that become worse in spite of treatment and where the diagnosis can be made in no other way would be guilty of gross neglect.

The following brief report of cases, which are not picked but are taken as they came, shows the multiplicity of lesions which may be caused by a blow upon the abdomen as well as the frequent difficulty of immediately making a diagnosis.

CASE I. L. M., boy of twelve (2) years, was run over by a baker's wagon, both wheels going over his abdomen. When seen right after the accident he was in considerable pain. Physical examination: Pale, in condition of moderate shock. Pulse, 120. Pupils equal and reacted to light. Tongue protruded straight. Heart and lungs negative. No fractured ribs. Slight abrasions across upper abdomen and lower chest. Abdomen presents slight general tenderness and voluntary spasm. No shifting dullness in flanks. No localized tenderness. Urine by catheter, clear. No fracture of the pelvis. Hot flaxseed poultices were applied to his abdomen and his pulse rate recorded at frequent intervals.

The condition of shock and the abdominal spasm at entrance made a diagnosis of some intra-abdominal lesion seem quite probable. His condition, however, steadily improved under treatment and he was discharged from the hospital in three days.

CASE II. F. J., seven and one-half years; male, fell to the ground from the roof of a three-story building. Says he was at first senseless. Physical examination: Pupils equal and reacted. Facies normal. No heaving or Babinski. Tongue protruded straight. Throat negative. Heart and lungs negative. Pulse rate about 120. Knee jerks normal on left, not sought on right. No ankle clonus. No fracture of the spine or ribs. Moderate general spasm of the abdomen, especially in the epigastrium and left upper quadrant where there is a little tenderness. Hot applications were applied to the abdomen and his pulse frequently recorded.

Rupture of the liver seemed a very probable diagnosis and was tentatively held for a few hours when it was found that the flaxseed poultices had done away entirely with all abdominal spasm. He was discharged from the hospital at the end of four days.

In both of these cases it was impossible to tell at once whether there was any intra-abdominal lesion or not. Especially was the diagnosis doubtful in the second case, for the spasm and tenderness were limited so closely to the region

of the liver that rupture of that organ seemed a very probable diagnosis. Both of these cases show how the application of heat to the abdomen by doing away with the spasm due to the constriction of the abdominal wall aids the surgeon greatly in determining for or against operation. The disappearance of the spasm considered together with a pulse rate which was not increasing made the diagnosis almost perfectly definite at once. Both boys received very severe blows and yet escaped serious injury.

CASE III. J. C., thirty-five years, an hour before entrance, fell off his wagon and the hind wheel passed over his chest. Physical examination: General condition fair. In some pain. Alcoholic odor to breath. Pulse, 84. Pupils equal and reacted. Tongue protruded straight. No signs of injury to head. Heart and lungs normal. Considerable tenderness to left lower side of chest. No fracture of ribs. Slight abrasion here of skin. Considerable tenderness all over the abdomen, most marked in splenic and suprapubic regions. Considerable involuntary spasm here. No dullness in flanks. Splenic and liver dullness not obscured. Shortly after entrance vomited two pints. Urine by catheter clear. When seen by me, two and a half hours later, pulse had risen to 120. He was nauseated and vomiting. Complained principally of pain in bladder region. Considerable spasm of abdominal muscles. No dullness in flanks. He was operated on as soon as the preparations could be made. Intestinal contents were scattered through the abdomen. A rupture of the colon was found at the splenic flexure. The patient died a few hours after the operation.

Here the accident was the same as in one of the previous cases but yet how different the result. The most marked feature of this case just before operation was the pain over the bladder with frequent desire to urinate. This was very misleading when an attempt was made to determine exactly the nature of the intra-abdominal lesion.

CASE IV. A. D., thirty-three years, female, had been kicked in the lower part of the chest on the left by her husband, twenty-four hours before entrance. The pain was slight at first, but by night prevented her from lying on the left side. Physical examination: Patient lay on right side with knees flexed. Considerable shock. Skin cold. Mucous membranes pale. Pupils contracted and reacted but slightly to light. Lungs normal. Heart sounds faint. No murmurs detected. Pulse at wrist counted as 90, but very weak, of poor volume and tension. Abdomen lax and protuberant. No muscular spasm. Tenderness in left upper quadrant where an indurated mass was felt. Free fluid in the abdomen. Leucocyte count, 8,000. Patient was operated upon immediately. The spleen was found ruptured and the abdomen was full of blood. Splenectomy was done and the patient recovered. Case reported in *Boston Medical and Surgical Journal*, Oct. 20, 1904.

CASE V. B. F., twenty-two years, male, fell off a cliff twenty-five feet. The fall was broken by a tree. Walked to the very edge and came home. Taken to the hospital. Physical examination: General condition not very good. Pulse 104, all at 100. Quality of pulse variable. Tongue protruded straight. Pupils equal and reacted. No signs of any cranial injury. Heart and lungs negative. No fracture of ribs.

Extremities normal. Abdomen shows considerable general tenderness, most marked in left upper quadrant. Considerable spasm on left. Dullness in left flank. Urine free from blood. A laparotomy was done at once and a fractured spleen removed. The abdomen was half full of blood. The patient made a satisfactory recovery.

One of these patients received a blow certainly of no greater severity than Case I or II and yet suffered a grave abdominal injury. The absence of any muscular spasm in this case (IV) is of interest and would easily at first throw the attending surgeon off his guard.

CASE VI. D. M. L., adult male, was stabbed in the abdomen about 8 p.m. Physical examination: 9 p.m., great shock. Very pale, anemic, perspiring freely. Skin cold and clammy. No signs of injury to head. Pupils equal and reacted to light. Tongue protruded straight. Mucous membranes very pale. Lungs not examined. Pulse, 76 to 80, poor volume and tension. Abdomen slightly distended. Slight dullness in both flanks, otherwise tympanic. No obliteration of liver dullness. Very slight general spasm. No localized tenderness. About one inch above umbilicus and one-quarter inch to left of median line a very small punctured wound. Extremities cold, reflexes normal. Patient refused operation. About 3 a.m. found in marked state of collapse. Pain throughout abdomen. Respiration difficult. Cold. Perspiring freely. Pulse, 140, irregular, poor volume and tension. Considerable abdominal spasm and general tenderness; increased dullness in both flanks. Patient then consented to operation. At operation it was found that the stab wound had not entered the abdominal cavity. An enormous amount of blood was found principally behind the posterior layer of the abdominal peritoneum. The source of hemorrhage could not be found and the patient died. At the autopsy the source of the bleeding could not be found till all of the intestines had been removed and then a hole was discovered in the inferior vena cava large enough to admit the tip of the finger.

CASE VII. A. A., six years, male, was run over by a team, the wheel passing over the left thigh and pelvis. Physical examination: Skin and mucous membrane pale. Pupils equal and reacted. Tongue protruded straight. Very restless. Constantly asking for water. Grunting respiration. Heart and lungs negative. Abdomen moderately distended and somewhat tender throughout, especially on the left side. Dullness in left flank and in suprapubic region. Some spasm, especially on left side. Temperature normal. Pulse, 120. Fracture of left femur and some abrasions. Pulse rose to 140 and 150. Catheter withdrew a half ounce of bright red blood and later an ounce of bloody urine. Four ounces of boracic solution put into bladder and all returned blood tinged. Pulse 160. Abdomen had become distended and somewhat generally rigid. Change in the percussion note in the flanks when patient turned. Exploratory laparotomy was done. Intestines, bladder, kidneys, liver and spleen were all examined by sight or touch without finding any lesion. There was no retroperitoneal hematoma about the kidneys. The patient developed a bronchopneumonia the next morning and died. Before death, was very restless and thirsty. Urine by catheter was high colored, but contained no blood. A partial autopsy was done. The left kidney was ruptured and lay in the midst of a moderately large hematoma. The left lung showed evidences of the bronchopneumonia and also of trauma.

This case shows how, in a certain number of cases, the diagnosis can be made only by an exploratory incision. In this particular case the criticism may be justly made that had the boy not been operated upon he probably would have lived. Because of such dangers as pneumonia, resulting from an exploratory incision, which is usually considered of such slight severity, one should not operate indiscriminately to settle the diagnosis, but should reserve it for those cases which steadily grow worse in spite of treatment and then should not delay a moment.

From these few cases it is obvious that a patient who has received a blow upon the abdomen of any degree of force is in a critical condition and must be under careful observation. For on slight changes in the physical condition depend the diagnosis and often his life. The absence of muscular spasm does not rule out an intra-abdominal lesion while its presence makes such a condition the more probable. Hot applications should be applied to the abdomen and the pulse recorded at frequent intervals. The urine should be drawn by catheter, if the patient is unable to pass it. Should the pulse rate steadily rise even only slowly, or the abdominal spasm persist or the urine be bloody, the case becomes distinctly surgical.

This short paper is not intended to point out when or when not to operate, but to insist on the severity of this class of cases and to make a plea for an early working diagnosis by a surgeon.

BRAIN ABSCESS. OPERATION, RECOVERY.*

BY PHILIP HAMMOND, M.D., BOSTON.

THAT the mortality in cases of brain abscess is heavy, we all know. A glance at the figures of two of our leading hospitals serves merely to emphasize this statement.

Harris¹ reports that for the ten years from 1895 to 1905, there were seven cases of brain abscess at the Manhattan Eye, Ear and Throat Hospital, all of which were fatal.

A careful examination of the records of the Massachusetts Charitable Eye and Ear Infirmary for the same period shows nineteen cases, with two recoveries. Of these nineteen cases, it has been my good fortune to operate upon five, and I am able to show you one of the patients this evening. The other successful case was reported by Dr. Jack recently.¹

J. K., laborer, married, forty-one years old, a resident of Haverhill, presented himself at the clinic of the Massachusetts Charitable Eye and Ear Infirmary, July 7, 1905, for relief from severe earache.

History.—Typhoid fever, at nineteen. Said to have had a discharge from the right ear for six weeks about a year ago. Severe pain in the right ear during the last seven days. No otorrhea. Mastoid tenderness for three days. No vomiting or chills, and no dizziness.

Present condition.—Right drum membrane swollen and bulging; no perforation visible. Slight tenderness at the tip of the mastoid. The hearing for the spoken

*Read at a meeting of the New England Otological and Laryngological Society, Nov. 17, 1905.

¹ Laryngoscope, July, 1905.

voice in the affected ear was three feet, and the Weber was heard in that side.

After freely incising the drum, the patient was placed in bed, the ear douched, and the ice-coil placed on the mastoid.

On July 9, two days after admission to the hospital, he was found on the bathroom floor, unconscious. On recovery, he answered questions clearly, and said that he suddenly lost consciousness while washing his face. He did not remember going to the bathroom, however, until several hours later. When seen a few minutes after the fall, he had labored breathing, and a slow, full pulse. In addition to this there was a bad bruise on the upper lip. He complained of severe pain on the right side of the head.

On the day following the fall the record states that he vomited several times during the night, and complained of being dizzy. There was still some pain radiating over the right side of the head. The pupils were equal and contracted to pin-point size. They reacted very sluggishly to light and distance. The superficial reflexes were equal. It was noticed that there was a foul odor to the discharge from the ear. Examination of the eyes showed no changes in the retina. There was apparently some tenderness on pressure over the cervical vertebra.

He was seen at this time by Dr. Putnam. Although the symptoms were vague, it was decided that it would be better to operate and find out the exact condition of affairs.

Operation.—He was accordingly etherized on this, the third day after his admission to the hospital, and the mastoid exposed in the usual manner. The cortex was found to be sclerosed to such a depth that all attempt to reach the antrum was abandoned. The mastoid tegmen was rapidly removed, permitting the escape of a quantity of very foul pus. A necrotic area was discovered extending through the roof of the middle ear, and over this a small perforation was found in the dura. A director passed upward through this hole allowed a large amount of foul pus and disintegrated brain tissue to escape. The opening in the dura was enlarged, and a probe passed upward 2 to 3 cm. into a large cavity in the temporo-sphenoidal lobe. To secure good drainage the dura was then lifted away from the base of the skull, and the whole roof of the temporal bone taken out. A wick of iodoform gauze was passed into the cavity in the brain, and the mastoid opening packed with the same material. The length of time consumed in the operation was forty minutes.

Following the operation the patient did remarkably well. Drainage was maintained throughout by means of the gauze wick, and at no time was there any question of insufficient drainage, nor was there any hernia cerebri. The patient was up and about the ward on July 24, exactly two weeks after the operation and from that time on convalescence was rapid. The sinus in the brain was closed by Aug. 10, and the patient was discharged from the house Aug. 22. The records state that at this time there was slight discharge from the middle ear, and the posterior wound was fairly clean. The general condition of the patient was excellent, and the hearing in the affected ear practically normal.

Remarks. Among the points of interest in this case may be mentioned the abscess situated, the fact that perfect drainage was established from below, instead of through the squamous portion of the temporal bone and the use of a gauze drain.

Authorities are divided in their opinion as to the most desirable route by which to approach

the abscess. In many cases it would seem better to at least thoroughly explore the dura by removing portions of the tegmen, especially where any portion of the latter is diseased. Particularly is this method of operation applicable where doubt exists as to the portion of the brain involved, as it is as easy to uncover the cerebellum from this point as the cerebrum. Advocates of the opening through the squamous portion of the temporal bone claim the advantage of entering the abscess cavity through a clean surgical wound, and believe that much better drainage is established, because of the larger opening. That a sufficiently large opening can be made through the roof of the temporal bone was quite apparent to all who saw the wound in this case, and there was absolutely no tendency toward hernia of the brain, a complication which becomes very troublesome where a plate of bone is removed from the side of the head.

In regard to the drainage there is also a difference of opinion, some operators relying upon drainage tubes, either hollow, or filled with gauze, and others using gauze alone. In my cases the latter has given most excellent results, and apparently keeps the wound in a cleaner condition.

A CASE OF ACUTE MENINGITIS. OPERATION, RECOVERY.*

BY A. CROCKETT, M.D., BOSTON.

Mrs. E. C. was brought to the Eye and Ear Infirmary in an ambulance in my service, July 2, 1904. The history was that she had had a running right ear since childhood, which had only been treated at long intervals. Nine months before I saw her she had had an attack of severe pain in the head, accompanied by tenderness over the region of the ear and mastoid. Three months later she had another attack of severe pain on the right side of the head accompanied by nausea, vomiting and vertigo. During this attack she was four weeks in bed.

Nine weeks ago she again had an attack of severe pain in the right ear and her family practitioner attempted to do a paracentesis upon the ear. Two days before admission the head ache, which she had had more or less constantly for the last two months, became very severe and she had a loss of consciousness lasting about twenty minutes. Since this time she has had occasional attacks of nausea and vomiting with dull and transient attacks of delirium. She had been confined to her bed through the whole of this time.

The patient was brought in to the hospital in an ambulance in a semi-comatose state and in general appearance was gray and septic. She complained of nausea, vomiting and severe occipital, frontal and right parietal headache. Her temperature was 102° and on examination of the fundus showed double optic neuritis. The right ear was exuding foul smelling exudate, and was completely filled by a large firm red polypus which projected out beyond the concha.

The patient was immediately prepared for operation. Under ether the polypus was hastily snipped off with a large snare. A large amount of pus was washed out of the tympanum and a best probe could be passed into the middle cerebral cavity. A circular incision was then made over the area behind the right ear, and

* Read at a meeting of the New England Otolaryngological Society, August 17, 1905.

with a chisel and rongeur, an opening about two centimeters in diameter. The dura bulged and did not pulsate; it was opened with considerable escape of cerebrospinal fluid; distinct yellow lines of pus could be seen parallel with the vessels on the surface of the brain. The brain was probed downward, forward and backward to a depth of 3 cm, and nothing found. A gauze drain was then placed inside the dura and pushed down towards the petrous portion of the temporal bone, the other end was brought out and through the external skin flap which was then sutured.

The patient made a rapid and uneventful recovery and was discharged from the hospital three weeks after the operation.

This is the second case of acute suppurative lepto-meningitis which I have seen recover, and I believe that many of these cases could be pulled through if operated on at once and a drain put into the subdural space. The cerebrospinal exudate along this drain will relieve the increased cerebrospinal pressure which is what kills most of the patients at once.

In clinics we often see cases that by sheer force of their own vitality survive the first stages of the disease and then pass into a chronic condition in which they may live for weeks. These are the cases that an early operation may pull through. In the case just described the mastoid was not opened at all for the reason that the infection seemed plainly via the roof of the tympanum and the patient was in such poor condition that I did not feel justified in adding to her shock by doing a mastoid operation in addition to the trephining. Her middle ear has since been treated by the ordinary method and is now nearly dry.

GENERAL LYMPHO-SARCOMA ESPECIALLY ACTIVE IN THE THROAT.*

PRELIMINARY REPORT.

BY F. F. EMERSON, M.D., BOSTON.

APRIL 30, 1901, Mr. W. was sent to me by Dr. P. and examination revealed the following condition: Patient, an American merchant, is forty-seven years of age, and was born in Boston. Denies venereal, tobacco or intemperance. Father died at seventy-five of cardiac disease, mother at seventy-four of carcinoma. One brother died of phthisis, one sister of scarlet fever, and one of typhoid fever. At eight years of age, Mr. W. had rheumatic fever which recurred annually for six or eight years. In 1898 he had an intestinal hemorrhage followed by fainting attacks. In 1899, fainting followed by vomiting of blood. In 1900 he developed hoarseness and experienced difficulty in talking distinctly. The *nares* are obstructed almost completely, apparently from collateral edema which does not contract under cocaine enough to give any view of the post-nasal space, or the turbinates. The uvula is club shaped and the size of a pecan. A ridge extends along the lateral walls of the pharynx which is smooth, of a cartilaginous feel and grayish color. Between these is a heaping up of tissue forming a rounded mass which interferes with deglutition. The eyelids are prominent and the conjunctivae, especially at the outer third of the upper lids, forms a partial fold over the eyeball. The lower conjunctivae are dotted with irregular

rounded projections. The bridge of the nose is broadened. The face pale and, except for the intelligent look and quick mentality, one would almost think of myxedema. There is also cervical and inguinal adenitis, but no change could be detected in the spleen or liver. The heart shows moderate hypertrophy with a systolic murmur at the base and an intermittent pulse. His general appearance is that of a man sick with some wasting organic disease. His weight has dropped from 154 to 130 pounds, and he has been subject to so-called bilious attacks frequently, which are followed by clay-colored stools.

His appetite is poor and he has a sense of fullness at the epigastrium accompanied by muscular weakness and general depression. The temperature is normal, his pulse 80 and it intermits about one in seven beats.

Diagnosis: A provisional diagnosis was made of syphilis and antileptic treatment commenced.

May 1, 1901. Examination of urine and sputum was negative. Blood: Hemoglobin 75%. White cells 6,800; red, 3,568,000. Increase in lymphocytes negative. Microscopical examination: This was made at the pathological department of the Boston City Hospital and was from a snipping from the posterior pharyngeal wall. Gross: Spreading growth on the posterior wall of the pharynx, growing down on two sides in ridges as large as the little finger. Piece taken from the growing edge low down. Microscopical: A round cell growth very much resembling lymphoid tissue, showing very few mitotic figures and of evident slow formation. It has in the most part a definite capsule but in places is infiltrating the muscular tissue. The clinical history must be relied upon to determine its malignancy; a large definite tumor growth would suggest sarcoma.

Oct. 22, 1901. Mr. W. had gained two and one-half pounds when he had an attack of acute rheumatism, lasting two weeks. His weight is now 127½ pounds. During this attack his hoarseness, dysphagia and swelling of the lids improved but returned as the rheumatism grew better. Nov. 7, weight 132½ pounds; Nov. 15, 133½ pounds, and Nov. 26, 134 pounds. Dec. 15, slight hemorrhage from the stomach and bowels. Jan. 23, hemorrhage; Feb. 15, 11 P.M., hemorrhage from the bowels, 12.45 and 1.45 from the stomach. The swelling of the eyes and throat diminished. Three days previous to these attacks he had yellow, watery dejections. No epigastric tenderness. The *nares* are now open, and he eats better, but is pale and weak.

March 4, 1902. The pharynx is more swollen laterally and at the lower third. He chokes regularly on trying to eat. The lymphatics in the neck, cheek and eyelids are more swollen. The eyelids at the outer third form a partial curtain over the eyeball. The uvula is two thirds its former size. His pulse intermits every seventh beat. Previous to this examination he had gained from 126 to 134 pounds. His uvula was decidedly smaller and I was loath to change his treatment, notwithstanding the microscopical examination, especially so, as his attack of acute rheumatism and four subsequent attacks of influenza had so interrupted my plans that it was difficult to draw definite conclusions in regard to it.

May 1, 1903. Mr. W. consulted a very careful and experienced observer who made a diagnosis of lupus and suggested arsenic. Beginning with one minim of Fowler's solution, this was increased to thirty, and the treatment extended over a period of one year. It was then omitted one year and resumed for two weeks, and again omitted. The first six months was interrupted by repeated acute infections, but at the end of the year, he was decidedly better. His throat was giving him little trouble, but he was thin and weak.

* Read at a meeting of the New England Otological and Laryngological Society, Nov. 17, 1905.

Sept. 25, 1905. Examination: Hic eyelids are slightly swollen for which he again consults me, but patient says they have not been so for over a year until now. The bridge of the nose is somewhat broad. The nares are free and the uvula is normal. The pharynx is pale and the right lateral wall is a little swollen. No glands, pallor or muscular weakness. No spleen. No hemorrhage for four years. Appetite good. Weight, 154 pounds (normal). The blood shows no abnormal cells and is otherwise negative. Oct. 26, patient has had a hemorrhage from the left nares which saturated two handkerchiefs, and the external swelling on the corresponding side of the nose has diminished, but not on the right.

Reports of Societies.

NEW ENGLAND OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.

MEETING HELD AT THE BOSTON MEDICAL LIBRARY, NOV. 17, 1905.

PHILIP HAMMOND, M.D., SECRETARY.

DR. E. A. CROCKETT read a paper on

SUCCESSFUL TREPHINING FOR ACUTE MENINGITIS.

and DR. PHILIP HAMMOND on

BRAIN ABSCESS: OPERATION, RECOVERY.

DR. J. J. PRENSAM: I regret very much that I was not in time to hear Dr. Crockett's paper, but I am understood the time of the meeting. I judge that the case was one of great interest, because the operation for meningitis has seldom been successful. It certainly should be the dream of the surgeons to eventually learn how to treat the brain more or less with the same success as is obtained in diseases of the abdomen and cavity.

With regard to Dr. Hammond's patient, whom I saw with him, I have very little to say, except that the case was a very obscure one as regards symptoms. When I examined him the question of abscess was discussed, but if I had not seen a very interesting case of cerebellar abscess a short time before, with Dr. Hammond, I do not know how strongly the idea would have been entertained.

It seems to me a very fortunate thing that both otologists and surgeons have shown the propriety of disregarding the sinus in taking off large pieces of the cranial bone. This is especially important with reference to operation on the cerebellum.

Abscesses in this region are extraordinarily silent and give rise to few symptoms, and the diagnosis must be frequently a matter of inference. If it is possible to attack the right half of the brain without danger, as doing much harm, this is still more possible as regards the cerebellum.

In the case of a patient of mine, recently operated on by Dr. Mixter, a good part of the cerebellum was seriously damaged in the search for a tumor, without unpleasant results. Of course there is some danger that septic material may be carried away, but the danger could, perhaps, be guarded against in some cases.

I think that every case of brain abscess should be studied with the greatest care, because I have had very few successful ones in this neighborhood. Dr. Jack, I believe, has had one, but in the history of Dr. Fyfe and Lar. I believe the number of successful

operated brain abscesses are very few. There are several reasons for this, and one of them is that it is sometimes difficult even when the abscess is struck, to know that it has been struck, because the pus is liable to be so thick and gummy that it will not flow through the trocar.

I should like to refer to one more patient. It has recently been shown that the subdural space, and even the brain, can be safely tapped in many places through minute openings in the skull without serious risk. Two writers, who have reported on this matter, refer to some eighty cases with about two hundred tapplings, and assert that even etherization is not always necessary. This method should prove of great value in the differential diagnosis of meningitis.

Is it not true that advantage has been gained in the treatment of ear troubles by the removal of very large pieces of bone? I would also like to ask if the tendency has not been to make very much larger openings through the skull than were made formerly in both kinds of cases; and especially with meningitis cases, if not done very early, would there not be a great deal of benefit to the patient?

DR. RICHMOND: Up to the present time I have had rather unfortunate experiences with my cases of brain abscess, all of them having died. Two of the cases are perhaps worthy of brief notice here in connection with Dr. Hammond's case and the remarks which Dr. Putnam has just made with reference to the obscurity of the cases and the difficulty of diagnosis.

The first case here mentioned I reported some years ago. The patient was a man in middle life who had gone to a general hospital for a slight pain in the head, accompanied with some ear discharge. After a few days' stay he was discharged at his own request, and on leaving the hospital in the afternoon, attempted to walk home, the distance being but a short one. As he did not reach home that evening, a search was made and he was found the next morning in a swamp, practically unconscious and was taken back to the same hospital at noon of the second day, totally unconscious and hemiplegic. Examination of the mastoid and tympanic cavity was negative. I then trephined with the usual round trephine through the squamous portion of the temporal directly above the tympanic cavity. The dura was dark in color, non-pulsating. It was incised, the opening extended about a quarter of an inch into the brain's substance and about two ounces of extremely foul pus evacuated. The patient recovered partly conscious, but lived only three or four days. It is probable that this abscess had become cystic for some time without producing any symptoms, and the case illustrates the always potential danger of a cyst of supplicative otitis media.

In the second case the cerebral symptoms suggested brain abscess and the tympanic cavity contained considerable polypoid degenerated material. The mastoid operation was done, such of the material as could be reached directly into the brain, through the round and evacuated. The difficulty here was one of drainage, and although I used rubber drainage tubes and drainage dressings, gauze was again to everything I could think of in order to get the discharge out of the head, and the discharge was so thick that it was not removed. I thought the patient would survive, but he died two or three days later. I think that in the case of death of a patient from brain abscess, the most stringent precautions were not taken. After death there was no further drainage, and two or three days later the patient was found dead in his bed, and I think there was no drainage. I think the case is a very interesting one, and I think it is a very early case of cystic degeneration of the abscess.

¹ See p. 103.

² See p. 102.

under apparently the same operative procedure. It seems to me often due to the fact that one has lasted a much longer time than the other and the amount of disintegration has become greater. It does not seem to me that in Dr. Hammond's case there could have been such an extreme amount of cerebral disintegration. The nearness of the abscess to the brain cortex and the length of time it has been in existence aid very much in determining the probable course of the disease. The nearer it is to the surface and the quicker diagnostic symptoms supervene, the better the chances for the patient.

I have had a feeling that all of my cases of brain abscess died because of faulty technique, and am encouraged somewhat by the fact that in the cases cited only two out of nineteen have recovered. I have also followed up Dr. Knapp's reports in New York and find that there, also, the mortality from brain abscess is very high. In every case where we have symptoms sufficiently definite I think we should explore for brain abscess and not be dissuaded therefrom by the fact that the mortality is so high.

DR. SPRAGUE: I would like to mention two cases which illustrate the points which have been brought up by Dr. Putnam and the others.

I had two women patients, both housekeepers, who consulted me at the hospital for headache and chronic otitis. I was not suspicious of intracranial complication, as there were no symptoms to suggest it, but operated for chronic otitis. The mastoid in each case was opened, and a fistulous tract was found leading through the roof of the mastoid into the abscess cavity directly over the roof of the mastoid in the lower temporal lobe of the brain. The abscesses were small ones, perhaps about as large as an English walnut. The cavities were curetted and packed with iodoform gauze daily until the cavities were finally obliterated, and the after-treatment was continued as is customary in cases of radical operations for chronic otitis media.

These cases are good illustrations of the obscurity of symptoms in brain abscess and the success obtained by operating through the roof of the tympanum.

DR. JACK: I should like to say one word about the operation for brain abscess. The majority of brain abscesses caused from middle ear suppuration are found in the temporosphenoidal lobe.

In the case to which Dr. Putnam has called attention, a large incision was made through the tegmen tympani. The evacuation of considerable pus was due to the opening (easily done by a knife) of about half an inch of brain substance. The question arose at the time of operating, whether trephining through the squamous bone was necessary for better drainage. It was not done as sufficient drainage seemed established and the danger of hernia of the brain was hereby avoided.

Dr. Hammond's case again goes to prove that trephining is not always necessary in this class of cases. In my experience gauze drainage has not proved a success. In three cases where attempts were made to keep the wound open with gauze, the patient did not do well as the cavity did not seem to be drained properly by the wicks, but after inserting a rubber tube in place of the gauze, drainage was practically complete. At each dressing the tube was placed a shorter distance into the opening until finally the abscess cavity was closed. [In reply to Dr. Putnam's question.] I certainly believe that the removal of large portions of bone has considerable to do with the success in many cases.

DR. CROCKETT: I had one case at the hospital where the man had a cerebral abscess. I probed his brain very freely without finding the abscess, and finally left in a drain. This gave him a great deal of

temporary relief and he improved in many ways, but finally died. It seems to me that I should operate in the way described in my report of this case, in every case of acute septic meningitis, if I could see the case within a few days of the onset.

DR. HAMMOND: The question raised by Dr. Richards also occurred to me. It has seemed to me probable that abscesses which lie near the surface, or those which perforate spontaneously, could more easily wall off infection of the brain tissue than those where long drainage routes have to be established.

The point that Dr. Putnam advances regarding the removal of large areas of bone I think an important one in such cases, as was very well shown in the boy with cerebellar abscess, to whom he refers in his remarks. This boy had a very large cerebellar abscess and it was necessary to remove a considerable portion of the occipital bone. After the abscess was evacuated the boy became very much better, probably on account of the relief from pressure, and I thought he would live, but at the end of three weeks he developed an encephalitis and died.

DR. F. P. EMERSON read a paper on
GENERAL LYMPHO-SARCOMA ESPECIALLY ACTIVE IN THE THROAT.³

DR. FARLOW: Several years ago I saw a patient, fifty years of age, who interested me very much. The soft palate was infiltrated and the posterior and lateral walls of the pharynx showed the same kind of smooth, firm growth as Dr. Emerson described. The condition was not in the least painful. The general symptoms were those of apathy, there existed a certain edema of the face about the eyelids, and also the cheeks, and she had a look of myxedema. I tried all kinds of local and general treatment without success.

I removed pieces of the growth, which were examined microscopically, but this examination gave no satisfactory information. It was considered a mucous infiltration. This case was reported in the *Trans. Amer. Laryngol. Assoc.*, 1896, and I gave it the title of "A Possible Case of Myxedema of the Pharynx." I was ill at the time of the meeting, and the paper was read by title, and not discussed.

I made the diagnosis on the ground that there was myxedematous tissue in the pharynx, the fact that she had dry hair, a sealy appearance of the face, and that the general facial expression was one of myxedema. I do not suggest myxedema in Dr. Emerson's case.

DR. GOODALE: Dr. Emerson's case is very interesting, as it brings before us a class of affections which can be divided into three main divisions. Of these we find first the type of Hodgkin's disease beginning in the tonsils or lymph glands in the vicinity of the tonsils, and running a slow course. A second class is malignant lymphoma of the tonsil where the cells composing the growth are of the small round type, and there is much more rapid growth. The third type is lymphatic leukemia. The line of demarcation between these forms is often slight, clinically, in the early stage. A case which I have seen this week illustrates this point.

A man of forty had a swelling of the tonsil of five weeks' duration, the tonsil extending beyond the middle line and showing ulceration. A number of men had seen him in the West and called the condition Hodgkin's disease. The blood is normal except for slight anemia. Histological examination of this growth shows a very similar condition to Dr. Emerson's case. This case may, at any time, show changes in the blood characteristic of lymphatic leukemia.

I saw a case three years ago in consultation which represented the third type. A student showed sore

³ See p. 104.

of the bladder or of the urethra. The affection was a stubborn one, but the detection of the causes would help greatly in the selection of appropriate treatment.

PROSTATECTOMY.

Dr. W. D. HAINES, of Cincinnati, Ohio, said that two cases, aged respectively forty-two and fifty-nine years, with small indurated prostate with obstruction, occurring in his practice, did well after perineal section and the removal of the gland, in that the catheter was abandoned and a troublesome cystitis relieved. One of the cases suffered incontinence for a period of three months after operation and the cure was incomplete as residual urine was found in both cases, and this despite easy bladder access by the sound or catheter.

The author condemned the use of metallic instruments in prostates for diagnostic purposes, or for the relief of urinary retention, as the danger of perforation and infection far outweighed the meager information or temporary relief thus obtained.

One could confidently hope for complete cure in 30% of the cases submitted to prostatectomy, namely, release from catheter bondage, relief from bladder complications and restoration of urinary function. In his experience with perineal prostatectomy seven cases had been functionally cured, nine showed residual urine, some of whom had had attacks of cystitis and dribbling, and five of these were suffering from incontinence six months to one year and a half after operation. Two cases required secondary operation, one for stone, and one for perineal fistula, making a total of sixteen cases with ages ranging from forty-two to seventy-nine years without mortality. While these results were far from ideal, the unfavorable physical condition present in the majority of them would in a measure mitigate against criticism as to the final outcome of this series.

THE OPERATIVE TREATMENT OF TUBERCULOUS JOINTS.

Dr. HORACE J. WHITACRE, of Cincinnati, Ohio, advocated four kinds of operations for tuberculous joint disease. *First*, osteotomy for the removal of an epiphyseal focus. *Second*, erosion or arthrectomy of those cases, particularly in the young, where the focus was circumscribed and a fair amount of synovial membrane remained. *Third*, excision. *Fourth*, amputation. Osteotomy for the removal of a focus localized in the epiphyseal end of a bone was a most logical operation. Six cases of rather extensive tuberculosis of the knee were treated by arthrectomy or erosion. In four of these cases a complete cure of the disease with a useful stiff joint and good position was attained. In three of the cases a slight amount of motion giving some assistance to the patient in locomotion was regained. In two cases amputation was subsequently resorted to. These subsequent amputations occurred in patients who passed from his observation very soon after operation. They undoubtedly represented recurrence in a spot where the dissection had not been sufficiently thorough.

Excision for a tuberculous joint had been reserved in his practice for those cases in which the bone ends were damaged.

PRESIDENT'S ADDRESS.

The President, Dr. BRANSFORD LEWIS, in his address, considered two subjects: (1) Some unrecognized responsibilities of press and state in conserving health; and (2) the prophylaxis of the so-called venereal diseases.

He called attention to quick medical advertising in newspapers and magazines, and said that news man-

agers provided against discrimination frequently by making unworthy advertisements resemble as closely as possible the regular news material of the paper, or by setting it up as telegraphic matter. He thought the press was *particeps criminis* in presenting such fraudulent material. There was a widely disseminated and growing belief that matters pertaining to sexual physiology and pathology should be taught in a simple way to the budding youth of both sexes in the course of their regular education, in order to place them in a position to resist the temptations that beset young life, by the clearer understanding that such instruction would afford. He would make use of educational channels of all sorts to spread the information desired in a scientific, dignified, truthful and wholesome manner, and such instruction would be received in the spirit in which it was imparted. It was primarily to the education of the people to which we must look for providing either the required legislation or the belated impulse for self-respect and decency on the part of the newspapers in eliminating quack advertisements.

Another subject which he considered well worthy of attention was the determination of practical methods of protecting the people from the far-reaching and disastrous effects of those diseases generally termed venereal, but which were not uncommonly entirely innocent in their development. He referred to gonorrhea, syphilis and chancre. These diseases prevailed to an extent undreamed-of by the people and those in control of the public health of our country.

He believed nothing was to be accomplished by prolonging a discussion as to the propriety of legal control and regulation of prostitution. Instead of trying to do what was impossible, to corral and disinfect all prostitutes, he would teach the public the dangers of prostitution, the dangers of the diseases to which it led, the prevalence of such diseases in daily life, and how they were acquired innocently, how they were to be avoided, and the necessity of seeking relief from them as soon as possible when they were acquired. The campaign of education must be the chief reliance, and the medical profession, followed by the ministry, instructors in institutions of learning in general, philanthropists and leaders in public work, would have to be counted on as the purveyors of such education.

THE PRESENT STATUS OF THE SURGERY OF THE STOMACH.

This was the title of the address in surgery, which was delivered by Dr. W. D. HAGGARD, of Nashville, Tenn. A discussion relative to operation for stomach lesions now was similar to that in regard to appendicitis twelve or fifteen years ago. Then only the desperate cases were submitted to operation. It was so now with many stomach cases. This, however, must yield to the logic of results and in a short time the profession generally would advise early operation as they now well-nigh universally did in appendicitis. Improved technique, low mortality and satisfactory end results would inevitably do away with the empirical treatment of occult intractable stomach troubles.

The typical indication for operative interference was obstruction of the pylorus from an open or cicatrized ulcer causing dilatation of the stomach, with stasis of food. The short circuiting operation of gastro-enteric anastomosis found its ideal indication here, and had given the most beneficial results. It was the *fons et origo* of the present group of drainage operations, as well as other gastric procedures, and was altogether the most perfected and satisfactorily employed operative device. The other complications of ulcer requiring operation were pointed out as (1) perforation; (2) hematemesis of chronic ulcer. Operation was advised in repeated acute hemorrhage or in constantly recurring

The author made a special plea for extirpation in the treatment of cancer of the rectum as being the only procedure that would give hope of a cure. He touched on colotomy as the operation of necessity rather than the operation of choice and urged an examination in all cases where the rectum was involved, as in cases of hemorrhoids, where there were bloody stools, where there was painful defecation, and where there was constipation, and advised a microscopical examination in all cases where the neoplasm was developed. The author showed that the extirpation of a part or the whole of the rectum by the Kraske method was the ideal operation, and should be practiced only by those who have had experience in capital operations.

THE SURGICAL MANAGEMENT OF INJURIES OF PERITONEAL VISCERA RESULTING FROM VIOLENCE APPLIED TO THE ABDOMINAL WALL.

DR. JOHN YOUNG BROWN, of St. Louis, Mo., called attention to the dismal mortality in such cases, and emphasized the importance of their early diagnosis and prompt surgical treatment. He reported a series of six cases, which had come under his personal care during the past eighteen months, in all of which abdominal resection was done. Of the six cases, one recovered and five died.

An analysis of the cases led to one conclusion, namely, the importance of early diagnosis and prompt surgical treatment by abdominal section in all cases of abdominal contusion, in which there were present the slightest symptoms pertaining to injury of peritoneal viscera. If one waited until the classical symptoms of peritonitis were present, surgery promised little.

(To be continued.)

Recent Literature.

Surgical Aspects of Digestive Disorders. By JAMES G. MUMFORD, M.D., Visiting Surgeon to the Massachusetts General Hospital, and Instructor in Surgery at the Harvard Medical School. In association with ARTHUR K. STONE, M.D., Physician to Out-Patients, Massachusetts General Hospital, and Assistant in the Theory and Practice of Physics in the Harvard Medical School. The Macmillan Company, 1905.

The book consists of twelve chapters, to which an appendix, written by Henry F. Hewes, M.D., is added. The place usually given to the Preface is devoted to the "Argument." The first two lines of the Argument are as follows: "The purpose of this volume is an estimate of what surgery may accomplish in diseases of the abdominal digestive organs"; and the hope is expressed that the association of a surgeon and an internist has permitted the deduction of "certain broad and justifiable conclusions."

The purpose of the book has been admirably achieved; the consideration of the subjects is comprehensive but concise, and, as might be expected, the history of both diseases and methods of treatment has been given deserved attention. After a discussion of methods, five of the twelve chapters are devoted to the stomach, two to the bile passages, one to the pancreas, one to abdominal ptosis, and one to the appendix vermiciformis. This is a fair proportion, and it is commendable

that the appendix should be restricted to a single chapter. Frequent references suggest a careful and exhaustive examination of the literature, and opinions or methods of others are often quoted in the original words. The close relation and not infrequent interdependence of disorders of the stomach, bile passages, liver and pancreas are continually emphasized, and the claims of the surgeon are modestly but fairly and firmly presented. The limitations of all diagnostic methods and the difficulties of absolute diagnoses are sharply set forth, and just stress is laid on the extreme technical requirements of certain operative procedures on the stomach and the bile passages.

One hesitates to use the hackneyed expression, "This book should be in the hands of every," etc., etc., but in this case it is literally true. In it the physician may see that the surgeon does not claim everything in the abdomen, and the surgeon may read an impartial estimate of what medicine alone may, as well as may not, accomplish in digestive disorders. Once more is reiterated the too often forgotten fact that the decision *when* to operate should rest with the surgeon as much as *how* to operate, if he is to assume the responsibility of the case; but in the decision *when* to operate, the physician can render him assistance of the first value.

It is a genuine pleasure to read a medical book which possesses, apart from its technical value, distinct literary style and charm, as well as a careful regard for English grammar. Such a combination should not be infrequent, yet it is rarely found in modern American medical textbooks. The authors have given it to us in an exceptional degree, and merit our hearty thanks for so doing.

The letter press and the cuts are excellent, and the book is convenient and attractive, both in size and shape. It is to be hoped that it will attain the widespread success which it deserves.

A Text-Book of Clinical Diagnosis by Laboratory Methods. For the Use of Students, Practitioners and Laboratory Workers. By L. NAPOLEON BOSTON, A.M., M.D., Associate in Medicine and Director of the Clinical Laboratories, Medico-Chirurgical College, Philadelphia, formerly Bacteriologist at the Philadelphia Hospital and at the Ayer Clinical Laboratory of the Pennsylvania Hospital. Second edition, revised and enlarged. Illustrated. Philadelphia and London: W. B. Saunders & Co. 1905.

In eight months Dr. Boston has been called upon to revise his Text-Book on Clinical Diagnosis for a new edition. Seventeen pages of new matter have been added, and slight changes have been made throughout the text, chiefly in relation to certain chemical tests. Cytodiagnosis is given a more prominent place than in the previous edition. The subject in this book is approached largely from the laboratory standpoint, and as such occupies a somewhat different position from the merely clinical books on the same subject. The illustrations are numerous and good.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JANUARY 25, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications or referring to the publication, subscription or advertising department of this Journal should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 BROMFIELD STREET, BOSTON, MASS.

MASSACHUSETTS SCHOOL FOR FEEBLE-MINDED.

WE turn with interest each year to the annual report of this institution as representing a work well done for the most unfortunate class in the community. The high standard which this institution has set for itself is not only maintained year by year, but definite advance is made and opportunities demonstrated for the further development of the defective classes for which it cares. The year just passed has seen a large increase in the number of inmates, which for the first time has passed 1,000, of which nearly 900 remain at Waltham, and upwards of 100 are at the farm colony at Templeton. The trustees draw attention to the fact that the time is approaching to limit the number of admissions at Waltham, and this number is regarded as 1,000. It is, however, apparent that this number will soon be reached and passed, demanding that other provisions be made. It seems to the trustees the part of wisdom to establish a similar institution, possibly in the western part of the state, which should duplicate the methods and character of care given at Waltham.

It is interesting to observe the progress which has been made at the farm colony at Templeton which was begun a few years ago as an experiment. The crops during the year were prolific and the success of the plan carried out largely through the initiative of Dr. Walter E. Fernald the superintendent, is absolutely assured. A problem of far greater difficulty is the growing responsibility which has come upon the institution in the care of the criminal imbecile. The advent of girls and boys who, in addition to a

certain amount of weak-mindedness, are criminally inclined, has placed upon the management of the institution a responsibility which it was not primarily designed to bear. The influence of these morally imbecile persons is a source of great danger in many ways to the weak-minded children, and leads unless the greatest care be taken, to much demoralization. Such persons should be watched more closely than is ordinarily possible at Waltham, and the question is raised whether it would be desirable to confine them in a separate institution provided with proper means of restraint.

The report of the superintendent includes the usual details regarding the work of the school which may be read with interest by any one with humanitarian instincts. Of the farm colony at Templeton, Dr. Fernald says that this is the most satisfactory and successful department of the school, that the boys are happy and in the best possible health, and that there has been but one serious illness during the year. It is also noteworthy that during the five years since the colony was established no case of tuberculosis has developed. Under the heading "Classification and Methods of Training and Instruction" a valuable summary is given of the school work for which the institution especially stands.

The liberal policy of the institution, which has now been demonstrated for a number of years of permitting students' visits under proper conditions, is altogether to be commended. It is difficult to overestimate the value of one or several visits on the part of students in the more advanced classes of our medical schools. The opportunity is afforded of seeing, and to a certain extent studying, under the direction of the physicians in charge, a very large number of feeble-minded children and, fully as important, the methods of their care. Dr. Fernald has invariably shown the greatest willingness, even at some inconvenience to himself, to encourage such visits and has thereby set an example which may well be followed by other hospitals or institutions of similar character. The visits of students must ultimately be of distinct advantage to the cause of the feeble-minded by attracting them to take up the work of their care and treatment by modern methods. The field is broad and needs many workers.

THE ETIOLOGY OF LATERAL CURVATURE.

Is this issue of the *Journal* a very interesting preliminary report of a research which is expected to be of much value in the elucidation of the etiology

chanics of lateral curvature of the spine. Dr. Max Böhm, the author of this communication, has had a peculiar opportunity to study the subject on which he writes, in his capacity as director of the Mechanico-Therapeutic Department of the Massachusetts General Hospital. He has found that in persons suffering from marked lateral curvature there may be demonstrated by the x-ray a deformity in the vertebrae of the lower spine which leads through simple mechanical means to the physical defect which characterizes spinal curvature. Recognizing the fact that the upper part of the sacrum and the last lumbar vertebra are the foundation of the human spine, it follows that if any defect occurs through faulty development in this portion of the vertebral column, changes must of necessity take place in the superincumbent parts. If the malformation in this lower portion of the spine be asymmetrical, conditions are present for the recognized forms of lateral curvature. This observation, previously recognized in the cadaver, evidently has far-reaching possibilities when applied to the problem of the mechanism of the spine in the living subject. Dr. Böhm's report as given in this issue is preliminary merely, but that it is suggestive will not be questioned, and we shall await with much interest the promised detailed discussion of the question which is to follow. In the meantime the opportunity is given for others interested in the matter to confirm or to bring evidence in disproof of Dr. Böhm's claim. The subject is, as it were, open for general discussion through this preliminary report, and we have no doubt it will receive the attention which its importance warrants.

MEDICAL NOTES.

LEPROSY IN NEW SOUTH WALES. — A recent report on leprosy in New South Wales shows that during the year 1904, 14 persons were reported as suspected lepers; of these, 8 were ultimately admitted to the lazaret under warrants issued after inquiry into each case; but one patient died during the year, an adult male, born in New South Wales of European parents.

PROFIT IN GARBAGE. — The *Journal of the American Medical Association* comments on a paper in the *Scientific American* which discusses the disposal of garbage. The former method of dumping garbage at sea, as practised in New York, has given place in that city to its disposition along the shore in such a way that land may be made. By this means eighty-four acres of

land have been filled in, each acre being worth about \$10,000. Other refuse is used in various useful ways, so that what previously was a loss and expense has now become a positive profit to the city. The suggestions offered might, no doubt, be adopted with profit by other cities.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Jan. 24, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 30, scarlatina 41, typhoid fever 16, measles 199, tuberculosis 17, smallpox 0.

The death-rate of the reported deaths for the week ending Jan. 24, 1906, was 20.16.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Jan. 20, 1906, was 243, against 256 the corresponding week of last year, showing a decrease of 13 deaths and making the death-rate for the week 21.29. Of this number 128 were males and 115 were females; 239 were white and 4 colored; 149 were born in the United States, 91 in foreign countries and 3 unknown; 42 were of American parentage, 174 of foreign parentage and 27 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 36 cases and 3 deaths; scarlatina, 34 cases and 1 death; typhoid fever, 11 cases and 3 deaths; measles, 164 cases and 4 deaths; tuberculosis, 40 cases and 30 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 37, whooping cough 2, heart disease 27, bronchitis 8 and marasmus 4. There were 10 deaths from violent causes. The number of children who died under one year was 42; the number under five years, 65. The number of persons who died over sixty years of age was 60. The deaths in public institutions were 73.

There were 4 cases and 4 deaths reported from cerebrospinal meningitis during the week.

DR. BOWDITCH AN EMPLOYEE AS A FARMER OR A COACHMAN IS. — Our attention has been called to an editorial in the *Clinton Daily Item*, Jan. 20, of which we believe Mr. Parkhurst, a trustee of the Rutland Sanatorium, is the editor. We extract therefrom the following item: "Dr. Bowditch was an employee of the trustees, just as their farmer or coachman is, and the Board therefore supposed it was at liberty to hire him or dismiss him at its pleasure." Drs. Clapp and

to creed, race or color, and under such directions as the trustees or directors of said hospitals may prescribe by rules, and any patient received or admitted to said hospital whose financial means at command are not such as to enable said patient to pay for the necessary treatment and care shall be treated and cared for therein without any expense or charge whatsoever."

NEW HEALTH DEPARTMENT BOAT.—The new boat, "Riverside," of the Health Department, was successfully launched at Port Richmond, Staten Island, on Jan. 18. Mayor McClellan and other city officials were present, and the christening was performed by Miss Dorothea Darlington, the young daughter of the president of the department. The "Riverside," which is one hundred and thirty feet over all and has twin screws, is to take the place of the old "Franklin Edson," which has been worn out in the service, and is to transfer patients from different parts of the city to the hospital for contagious diseases on North Brother Island, in the East River. Her cost is \$75,000.

Obituary.

JAMES ARTHUR MAHON, M.D.

DR. JAMES ARTHUR MAHON was born in Truro, Nova Scotia, Feb. 7, 1865, and died in Boston Sept. 14, 1905. His preliminary education was received in the schools of his native town, in the academy at Pictou, and at Dalhousie College in Halifax. He graduated from the Harvard Medical School in 1896. Prior to and after graduation he served as surgical house-officer in the Boston City Hospital, finishing his course there in 1897. He was visiting physician to the Convalescent Home of the Boston City Hospital, to the Salvation Army Rescue Home and the Home for Incurables. He was a member of the Massachusetts Medical Society, the Alumni Association of the Harvard Medical School and of the Boston City Hospital. He was one of the board of trustees of the Roxbury Presbyterian Church.

Dr. Mahon was a physician of excellent ability and sterling character. He was painstaking and faithful in every detail of his work. He was conservative, yet never lacking in courage. His strong personality won for him many friends, both among his patients and his brother physicians.

The members of the Clinical Club desire to express their satisfaction as they recall their pleasant associations with him and their feeling of loss as they miss his genial presence. They desire further to extend their sincere sympathy to the family of James Arthur Mahon in their great bereavement.

The committee recommends, therefore, that this minute be placed upon the records of the

Clinical Club and that a copy be sent to the family of Dr. Mahon and to the BOSTON MEDICAL AND SURGICAL JOURNAL.

SAMUEL CROWELL, M.D.
EDWARD P. STARBIRD, M.D.

Episcellany.

TESTIMONIAL TO MR. HENRY H. SPRAGUE.

The senior staff of the Boston City Hospital appointed a committee of its three oldest members to prepare a testimonial to Mr. Sprague, for many years a trustee. A letter signed by sixty-nine physicians attached to the hospital, and a silver bowl and platter, appropriately inscribed, were presented on New Year's eve, 1905-06. The letter was as follows:

MR. HENRY H. SPRAGUE:

Dear Sir.—We, the physicians of the City Hospital, on the completion of your thirty years' service as trustee, ask your acceptance of a modest keepsake as a visible token of our respect. Thirty years of service in our hospital, unrewarded in money, can have been only partially compensated for by the estimation in which we hold you. A trustee has not even the worldly reward of a physician to a hospital. We have practice, experience, the opportunity to advance our own knowledge. You have only the consciousness of duty done, of the public good insured. In this you do not stand alone; for a long line of trustees, for forty years, have given us much of their lives.

It is not too much to say, however, that you do stand, if not alone, yet pre-eminent, in conscientious service.

Integer vixit expresses, in terse Latin, your life in the City Hospital. Untiring in your efforts, you have helped to lay its foundations broad and deep in charity and in honesty. No one could have done more to elevate the standard of our duties, and to make our hospital the foremost municipal hospital in position and in reputation. As your character is inseparable from that virtue which is its own reward, so your reputation rests securely behind the unassailable barrier of useful, honorable and charitable works.

DAVID W. CHEEVER,
JOHN G. BLAKE,
OLIVER WADSWORTH,
and sixty-six others.

Correspondence.

A PATIENT'S SUGGESTIONS ABOUT HIP DISEASE.

BOSTON, January, 1906.

Mr. Editor.—Permit me, through your columns, to call attention to some details which I have found of great importance in the treatment of hip disease. I have been a sufferer for half a century from this dreadful affliction, always on the verge of collapse, and too often over the line, and if I had been earlier acquainted with the following points, life would have been far happier and more useful.

Great care is always necessary. For instance, I have had attacks involving weeks in bed, brought on by reclining baths in too short a tub, by sitting in an armchair too narrow between the arms, by a jar in stepping from a high step, and oftentimes by walking too far. There is little pain of the common kind to warn one. Some attacks are heralded by a sensation like a blow on the hip while walking, followed by powerlessness, so that the sufferer has to stand perfectly still for some minutes. Often there is a local nervousness and generally a sore spot

before or behind the hip-joint in the morning, and these warnings mean a rest at once before the attack gets beyond control. The worst symptom is a series of convulsive muscular jerks or spasms which come on at going to sleep, or soon after, sometimes so violent as to shake the bedstead and be felt in the room below, and these attacks are so very bad that it may be months before the following exhaustion passes off. They can be checked to a great extent, and if they are, the attack will probably be very slight, but if they are not, the result is likely to be very serious. It is on this point that I wish to give my experience, for I have found that many good physicians do not give the needed advice.

Some of the remedies that I tried may be easily disposed of. Electricity administered by a skilled physician of standing was injurious. Painting with iodine and with ammonia and covering with porous plaster had no good effect and interfered with more efficient remedies. Massaging and rubbing with various liniments proved injurious. Blisters applied directly over the inflamed spot made it worse. I could not be sure whether an application a handbreadth lower down was good or not, but thought it slightly beneficial, probably due to its keeping me still by its soreness. One autumn, when there were indications of a winter in bed, I had a seton put in by an unwilling surgeon. It was sore, and I am told dangerous, but it worked well, and I was free from any serious attack while it was in, and it was worth the risk. I did not repeat it, for after I learned the use of weight it was unnecessary.

Some things certainly did good. A couple of teaspoonfuls of bromide of soda taken in water in the evening were soothing. Applications of hot alcohol and water had much effect, and upon violent attacks generally a handkerchief wet with rum and water and covered with rubber cloth helped a good deal in getting to sleep. Most important of all is the extension weight in the first part of the night. The mischievous muscular contractions are largely prevented by applying tension to the main muscle crossing the hip in front. A towel folded lengthwise, drawn under the middle of the foot, folded across over the instep and again behind the ankle in a figure 8, with a cord at the bottom running over a bar or pulley at the foot of the bed to a three-pound weight, is a great relief. A canvas ankle cap and a wooden shoe may be used, or any device by which the weight plays freely. A feather bed should be avoided, and the mattress should be convex, with the bed support two inches lower than the calf and hip, and the hair pillow low. The room should be cool. The patient should be careful to avoid any overheating with too heavy bedclothes, or by wool next the skin at the critical moment of getting to sleep. He must, of course, lie on his back. He can usually take the weight off safely after two or three hours and draw on more bedclothes. I found hammocks and low chairs dangerous. A Morris chair or a cane-seated stamer chair was best. The chair used at the desk or the dining table should be some inches higher than an ordinary chair, preferably raised by a rubber cushion.

I have known some women to profit by a steel supporting splint. I tried three or four without much success. The Sayre's splint could not be attached firmly enough to stand walking round much. The only one that worked ran from a brass half-sole inside the shoe, with an ankle joint and a knee joint, the latter springing a trifle past the center and so working well without any lock. The upper end was in a cross-plate fitting above the hip joint with a padded rubber tube covered with a handkerchief changed daily, passing from one end of the plate down between the legs up to the other end of the plate. There was a sliding joint so arranged that by pressing a small toggle-joint the splint could be shortened or lengthened three quarters of an inch, and thus was quite necessary, in order to be worn comfortably with it on. It was held in place by a belt at the waist, padded steel arms and straps at the thigh and calf, and the shoe at the bottom. It was worn inside the trousers and did not show conspicuously. A cane had to be used with it. It lessened the jar at the hip and relieved it of most of the weight, but I do not know that it was any better than crutches or two canes properly used, except in looks. Canes are seldom rightly used. The hand should be slightly curved,

so that the point where the hand rests is directly in line with the shaft; and the cane held with its head against the hip, the lower end, the handle, and the shoulder being in line. Properly handled, two canes will support nearly the whole weight of the body, and the invalid should acquire the habit of taking two whenever he is obliged to take a walk of any length.

The old-fashioned boots pulled on by straps were dangerous. I tried for some months those double boots where the foot is concealed in the ankle of the outer boot. They look better standing, but are not so safe.

It is better to have a support at the feet in bed. I tried first two half hoops crossed and tied so as to make a small dome supporting the bedclothes, but found it better to use a thin board, eight inches square, with a support behind to hold it nearly erect, padded and covered with linen. This holds up the clothes and also gives enough support to the foot to keep it from turning in, and thus relieves the other foot. If the feet are cold a foot-blanket can be wrapped around it with the end brought forward over the feet. The most important of these remarks are those about the night weight, about alcohol, and about the use of two canes. I hope that they may help some one.

H. W. H.

[Our correspondent is apparently in the third stage of hip disease. Had he been born later and thus profited by the advances in the treatment of hip disease of recent years, much of his suffering might have been spared. His experience may prove profitable and his hints useful to others. —Ed.]

CHARLES E. BUCKINGHAM, M.D.

ERRORS IN THE HARVARD MEDICAL SCHOOL HISTORY.

Boston, Jan. 20, 1906.

Mr. Editor: My attention was called by a friend to an error in the recent history of the Harvard Medical School, and this led to my finding another for myself. The statement is made in the biography of the late Charles E. Buckingham: "In his early professional career he was often in sore straits his means were small and he was without family influence. These difficulties did not discourage him. The struggle, however, left its scars, and one finds him afterwards a bitter and sometimes a censorious critic of men possessing those advantages which he lacked."

It is true that his father's business failure while he was in college necessarily cramped him, and it is conceivable that as his father had objected to his choice of a profession, he may have hesitated at asking for introductions that might easily have been given. To suppose, however, that this led to a mean jealousy of others is incompatible with his character, as I knew it in later life. This might be merely my opinion, but I expect to be believed when I say it is incompatible with his later relations to men of his own age, who were abundantly supplied with what he is said to have lacked. If better fortune in others had led to bitterness, bitterness should have been common toward all who had better fortune, but it was not. The writer of the biography may have seen him bitter, but has misinterpreted the facts.

The other error is more serious. When Harvard enlarged its faculty and adopted the plan of a continuous whole year session it won over Bacon, F. H. Clark, Buckingham and others to its teaching staff. This fact so crippled the Bowdoin Medical School that little is heard of it afterward. This misstatement is easily corrected. The original record of the corporation of that school is in my desk as I write. It shows that Dr. Buckingham was present at most of the meetings from the beginning to the end, and that he was clerk both of the meeting in 1855 which directed instruction to be suspended until the next meeting of all April 15, 1858. (Year was 1858, not 1857, in its edition of O. C. 19, 1857 gives the original appointment in Harvard as a matter of course. It is true that no action in 1856 can have determined a course that took place ten years or even seven years later.)

Truly yours,

EDWARD M. BUCKINGHAM, M.D.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JAN. 13, 1906.

* NOTE. — The populations of the Massachusetts cities and towns are estimated from the rate of growth from 1900 to 1905. The figures for Lowell, Taunton, Gloucester, North Adams and Clinton were allowed to stand in 1905, these places having shown no growth during the five-year period mentioned.

Deaths reported, 3,024; under five years of age, 871; principal infectious diseases (smallpox, measles, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption), 677; acute lung diseases 674, consumption 321, these figures having shown no growth during the five-year period mentioned.

From whooping cough, New York 3, Chicago 2, Baltimore 4, Lowell, Lawrence and Brookline 1 each. From scarlet fever, New York 7, Chicago 8, Providence 1, Boston 1, Brockton 1. From cerebrospinal meningitis, New York 26, Boston 2, Lynn, New Bedford and Newburyport, 1 each. From erysipelas, New York 5, Chicago 2, Baltimore 1, Woburn 1. From typhoid fever, New York 6, Chicago 9, Baltimore 5, Providence 1, Boston 5, Lowell 1, Lynn 4, Lawrence 1, Holyoke 1, Chelsea 1, Westfield 1, Revere 1. From measles, New York 15, Providence 1, Boston 3, Worcester 1, Cambridge 1. From

diphtheria and croup, New York 62, Chicago 11, Baltimore 4, Providence 3, Boston 3, New Bedford 1, Haverhill 2, Chelsea 1, Beverly 1.

In the seventy-six great towns of England and Wales, with an estimated population of 15,818,360, for the week ending Jan. 6, 1906, the death-rate was 18.3. Deaths reported 5,548; acute diseases of respiratory organs (London) 225, whooping-cough 120, diphtheria 70, measles 141, smallpox 0, scarlet fever 61.

The death-rate ranged from 9.0 in Walthamston and Rhondra to 30.5 in Preston; London 19.4, West Ham 18.5, Brighton 19.1, Southampton 15.6, Plymouth 15.9, Bristol 30.5, Birmingham 17.9, Leicester 17.7, Nottingham 19.9, Birkenhead 20.0, Liverpool 23.9, Wigan 19.1, Bolton 14.3, Manchester 17.4, Salford 18.0, Halifax 18.6, Bradford 19.9, Leeds 21.5, Hull 16.7, Sheffield 15.8, Newcastle-on-Tyne 16.7, Cardiff 17.9, Merthyr Tydfil 16.7, Kings Norton 11.5, Hanley, 21.2.

METEOROLOGICAL RECORD.

For the week ending Jan. 13, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING JANUARY 20, 1906.

JOHN E. PAGE, passed assistant surgeon. Ordered to the "Franklin," Norfolk, Va.

(Orders issued by commander-in-chief of Asiatic Fleet.)

H. G. BEYER, medical inspector. Detached from the "Wisconsin," and ordered to the "Ohio."

G. H. BARBER, surgeon. Detached from the "Ohio," and ordered to the "Wisconsin."

J. C. THOMPSON, surgeon. Detached from the "Lawton" and ordered to the "Cincinnati."

W. H. BECHER, surgeon. Detached from the "Cincinnati" and ordered to the "Lawton."

SOCIETY NOTICES.

PRIZE FOR BEST ESSAY ON ETIOLOGY OF EPILEPSY.—The National Association for the Study of Epilepsy offers a prize of \$300 for the best essay on the "Etiology of Epilepsy." Papers in competition must be handed in by Sept. 1, 1906.

THE BOSTON CITY HOSPITAL ALUMNI ASSOCIATION.—This Association will hold its annual meeting at Hotel Parkers, 270 Commonwealth Avenue, between Fairfield and Gloucester streets, on Wednesday evening, Feb. 7, at 6.30 o'clock. Dinner will be served at 7 o'clock, immediately after the business meeting. Dr. Charles H. Williams will preside.

WILLIAM H. ROBEY, JR., M.D., Secretary.

THE HARVEY SOCIETY, NEW YORK.—The sixth lecture in the Harvey Society course will be given by Prof. Lowells F. Barker, of Johns Hopkins University, at the New York Academy of Medicine on Saturday, Jan. 27, 1906, at 8.30 P.M. Subject, "The Neurones."

GEORGE B. WALLACE, M.D., Secretary.

RECENT DEATH.

EMERSON WARNER, M.D., M.M.S.S., died in Worcester, Dec. 24, 1905.

Address.

THE PROBLEM OF PSYCHIATRY IN THE FUNCTIONAL PSYCHOSES.*

BY EDWARD COWLEY, M.D., BOSTON.

IN the study of mental diseases it is important to find their true place in relation to other pathological conditions. Our conceptions of the nature of mental symptoms should be framed in harmony with the true principles of general pathology. These are essential requisites for the progress of psychiatry. I shall try to present some considerations to this end in discussing my subject: The problem of psychiatry in the functional psychoses.

It is essential here, as in all such inquiries, to have a clear understanding of the terms of the problem; words and phrases and the formulae of principles should have correct and definite meanings. Our ideas may be embodied at first in words which seem to express exactly all that we know; but as our conceptions tend to outgrow their verbal expressions these may gain the larger import and lose the narrowness of their derivations; or being used in an earlier and more or less restricted sense, they hamper thinking in the shackles of authoritative phrases that obstruct reasoning, and single words may perpetuate error and lead to confusion of interpretation and discussion. The dicta of general principles accepted as fundamental may sometimes harbor hidden fallacies and prove to be untrue after having long retarded process. It is a necessary part of this discussion to examine first some definitions and the formulae of certain accepted principles and the doctrines drawn from them.

The terms in which the present subject is expressed contain no ambiguity as to its meaning to lay down the proposition that the problem of psychiatry is to be found in the functional psychoses, meaning here mental diseases. But something needs to be said defining the true province of psychiatry; and the words "functional psychoses" lead at once into the maze of difficulty surrounding the relations of functional and organic diseases. In the definition of disease as "any morbid deviation from normal health," the important distinction is drawn between organic or structural diseases in which there is a lesion or pathological condition of some part of the body, and functional diseases in which there is an irregular action of a part but without organic abnormality. But keeping to this distinction, it is a remarkable fact that the word "psychosis" is used in opposing senses in mental physiology and mental pathology. The physiologists, having regard to the normal processes, use "psychosis" as "equivalent to the mental or psychical element in a psychophysical process, just as neurosis refers to that aspect of the process which belongs to the nervous system." On the other hand, in psychiatry the word "psychosis"

is used pathologically and "designates an abnormal mental condition"; it is described as a typical form of insanity ("disease-form") which can be scientifically differentiated and correlated with a specific "disease-process," and the usage implies a structural change. In neurology "neurosis" is also changed from its normal functional sense in psychology and used to designate a "morbid or diseased condition." "Functional neurosis is a morbid affection of the nervous system known only by its symptoms, and without anatomical basis. It is doubtless true that an anatomical lesion of some kind does in each case exist, and the classification of diseases as organic and functional is but a concession to our ignorance."¹ These instances afford examples of looseness of usage in two most closely interdependent lines of research showing the disharmony between them that tends to confusion of understanding. It is allowable to speak of the neuroses, and the meaning is plain as referring quite exclusively to functional disorders; but to constitute a true psychosis, in the pathological sense, it must have a definitely differentiated symptom-complex that can be designated as a "disease-form"; this is commonly spoken of as a clinical "entity," and it implies a correlated "disease-process." We may speak of acute and chronic psychoses, or of organic psychoses, to distinguish the insanity due to cerebral disease. But the psychoses proper being conceived as real disease-entities, when in psychiatry we wish to speak of the group of minor and often temporary variations of the mental functions, parallel or corresponding to the neuroses in neurology, the word "functional" must be added and the term "functional psychoses" used as in the subject of this discussion.

THE POSITION OF PSYCHIATRY AS SHOWN BY CURRENT TEACHINGS.

The point of view of this inquiry is that of general medicine for one who, without predilection and looking for light on all sides, approaches the field of psychiatry and tries to understand its problems. In seeking the true place of mental diseases in relation to other pathological conditions, and in order to harmonize his conceptions with the true principles of general pathology, it is found at the outset that the functional psychoses are to be regarded as being in contrast with the psychoses proper associated with assumed structural changes and "disease-processes," or with definite organic diseases of the brain. Here, as in general medicine, this distinction of functional and organic disease appears to be an expression of the dominance of morphological conceptions in medical knowledge. Diseases due to obvious structural changes can be understood and subjected to treatment and surgery; but the bodily diseases called "neuroses" for which there is no pathological anatomy constitute a very large group.

Although there is a greater reason for this being true also of functional mental diseases, the

* Address presented by Dr. Edward Cowley, chairman of the Section of Psychiatry of the International Congress of Arts and Sciences at St. Louis, September, 1904.

¹ Baldwin, *Theory of Phobias and Neurosis*.

quirer finds in the psychiatry of the time small interest in them. It is a very old idea that the different forms of insanity may be explained by the study of the brain and its degenerations. The history of modern psychiatry shows that it has given great emphasis to these morphological conceptions by its precise methods and achievements in histological investigations of the brain. In recent years the German schools have been the centers of interest. The environment of their origin had pre-eminently the morphological stamp. Thus the effort to determine definite "disease-forms" and "disease-processes" has been a distinctive characteristic of modern teachings in the search for anatomical correlations and explanations. The application of the scientific method in clinical study has been most fruitful of admirable results. The "disease-process" assumption has been stimulating and helpful as a spur to morphological investigation, which all agree should be carried to the utmost. But with the inheritance of such conceptions the modern movement has been characterized also by the continuance of the quest for mature forms and types and for their systematic classification. The pathological principles being embodied in the designations "disease-form" and "entity" and "disease-process," the consistent use of these has implied that every such pathological process should have its cause, course and outcome. A psychosis thus constituted is held to present the attributes of scientific truth, although some actual morphological characters that furnish complete and proper proof may yet be wanting.

While these teachings have been taking form in the last twenty years, the influence of modern psychology has been felt and is becoming apparent, especially in the last half decade. Although psychological studies of mental functions are viewed with much of the same distrust as before, the experimental method, in its clinical use in psychiatry, excites interest by the objective character of its results; they have the value of observed and measurable facts of function which may contain the promise of being ultimately traceable to facts of structure.

The present results of this movement are exceedingly interesting and promising, although it is true that there is much diversity in the products of these methods of study. With the increasing number of observers the more variations there appear to be in the interpretation of the phenomena. This is shown in the differentiation of named "disease-forms," and by a comparative study of some new classifications.² This, however, is a hopeful stage of progress. In the extreme view it has been held to be unreasonable that any conclusions can be drawn from the psychical activity of a diseased brain; psychological explanation is of no value, it is said, without an objective measure in definite "disease-processes" in the cortex. According to other views, in which the conception of a "disease-process" is still fundamental, conditions that do

not lead to deterioration are conceived to be of a "special type"; and a "biological entity" is conjectured as representing "a special kind of disease-process or disease-principle." Again, under broader conceptions, it is held that more than one point of view is needed to do justice to psychiatry, and a special psycho-pathology is founded upon normal psychology. But this meets with criticism as giving undue prominence to psychological distinctions inconsistent with a true medical conception of disease.

The influence of the new German schools has been strongly felt in other countries. But the inquirer, extending his survey in these directions, finds that the cotemporary interest in the physiological aspects of psychiatric problems has not waned, though they are somewhat overshadowed. In Italy, for example, Ferrari has studied the pathology of the emotions, as has Féré in France, where Ribot has done the most to elucidate the relation of mental experience to the personality, and Janet has made his remarkable contributions to future psychiatry by the analysis of mental instability in the borderland of insanity. The British alienists have conservatively given attention to functional as well as to anatomical conceptions, notably Mercier. Hughlings Jackson has magnified his distinction as a neurologist by his recognition of the importance of the physiological factors in nervous and mental disease; his method of reasoning from functional characteristics to interpret structure, instead of inferring function through proofs in structure, is now attracting renewed interest.

These English views have long held a like formative place in America, where they have not lost, but have sustained their force during the decade since the introduction of German teachings. Attention was first attracted especially to Kraepelin and his methods at the Heidelberg clinic with a consequent intensification of interest in morphological conceptions qualified by clinical observation. The painstaking studies of Meyer and Hoch approached the subject from the neurological side loyal to the scientific method; through their work the conceptions of Kraepelin were submitted to the tests of practical co-operative study and experience with results anticipating his own later simplifications of "disease-forms." There was also, not only the establishment of collections of admirable clinical records, valuable for further study and analysis in future, at the McLean Hospital and the Worcester Insane Hospital where this special work began, but the extension of this clinical method to many other hospitals. Later in the movement came the different interpretations of psychiatric problems by Wernicke and Ziehen, — the latter with an especially hopeful attitude toward psychological explanations. There has appeared a tendency to change in the views of these German teachers, of whom it is said they "have emancipated psychiatry from the peculiar position of an adjunct to neurology," — a position for which the claim has long been made and is not yet yielded.

² Meyer, A.: *A Few Trends in Modern Psychiatry*. The Psychological Bulletin, vol. i, 1904.

In the outcome of the decade in America the intensity of the new teachings is being qualified by independent studies of the problems involved, and the continuity of the current of earlier views here has been maintained. This former trend has persisted not only in psychiatry, but it has appeared in neurology which was formed in, and has held to, pronounced morphological conceptions. Dana, Putnam and Prince, for example, have taken special interest in the physiological and abnormal aspects of mental phenomena. Herter has made the most noteworthy contributions to the future understanding of mental as well as nervous diseases, by studies of the chemistry of pathological physiology and the disorders of nutrition and metabolism in seeking the fundamental principles of practical therapy. Traceable here, as in general medicine, is the influence of the immensely important work of Chittenden; while this has little or no place in German teachings of neurology and psychiatry, the chemical side of the composition and activity of nervous tissues is receiving attention in England. In recent years, through the special studies of Mott and Halliburton, which, however, relate distinctly to changes in structural disease. In America, the trend toward functional conceptions of mental pathology became embodied, with a special motive inspiration from general medicine, in the work of the McLean Hospital more than two decades ago. Early in this period, under the added influence of the new teachings of physiological chemistry, the purpose was developed which has led, in the last half decade, to Folin's chemical investigations of disordered metabolism in immediate connection with the clinical study of the physical conditions and treatment of the insane; the parallel development, on both physical and mental lines, of the original purpose there is also finding its prime expression in the recent establishment of another clinical laboratory in which Franz is applying the physiological and experimental methods of the trained physiologist and psychologist. This particular development of the tendency to studies of the physiological aspects of psychiatry has been characterized throughout by its essential purpose of seeking guides for treatment of the physical conditions associated with functional mental disorders.

It appears that the turning away from the barrenness of histological provings is becoming general; the improvements of the clinical method and psychological experiment are inevitably drawing attention to the closer observation of the individual patient, and to the better study of the minor causes of his mental variations; this means a trend toward physiology. It is a safe prediction that pathological physiology is to be called to render such aid to psychiatry as it is giving in general medicine; and that the extraordinary advances in pathological chemistry will become available in mental diseases.

Such are some of the considerations suggested by a survey of the present aspects of the field of psychiatry. The changing attitude of psychi-

atry toward psychology is of great significance. These circumstances guide the inquiry into the conditions and causes of the present position of psychiatry.

THE RELATION OF PSYCHIATRY TO GENERAL MEDICINE.

Psychiatry belongs to general medicine.³ This view has been presented in the annual reports of the McLean Hospital since 1882;⁴ my first statement of it, in the report of that year, was to the effect that the physiological basis of the treatment of the insane lies in the fact that the normal functions of the cerebral organ may be only temporarily disturbed or only partially impaired, whether by transient disorder or pathological change; and the consequent fact that, in most cases, some degree of normal function remains. This principle was stated to be in accordance with the most important gain of modern pathology, the modern conception that "Disease is, for the most part, normal function acting under abnormal conditions."⁵

Mental diseases, in their study and treatment, include more than is contained within one branch or department of general medicine by having to deal with the mental effects of pathological conditions of the whole body; psychiatry is not limited especially to the nervous system with its central organ, which has functions of a wholly different and higher nature than those of any other organ. There are functions of the brain other than the common ones of receiving impressions and reacting uniformly upon them like a reflex mechanism; by its mental function it receives impressions, retains and recalls its conscious experiences, selects from and rearranges them, and in new and orderly forms initiates and controls the processes of motor expression. The psychiatrist newly attempting the precise study of mental symptoms is confronted at the outset with the oldest of problems, the relation of mind and body. If he turns to physiology and neurology for light upon the physiological terms, mental and physical, of his problems, he meets everywhere such statements as that of Wundt: "In matters psychological the naturalist can only affirm that psychological phenomena run parallel with physiological facts, but that on account of their different natures he has no prospect of ever bridging the gulf between the two." Edinger⁶ writes: "We have no idea how it happens that a part of the work done by the nervous system leads to consciousness." Lloyd Morgan⁷ offers the following practical conclusion: "One of the difficulties is that of conceiving how mind can act on matter, or matter on mind. Let us at once confess our ignorance of the nature

of the intimate relation of the one to the other. But certainly in many cases, the observed facts show that, our ignorance notwithstanding, they *are* somehow related. . . . And since we cannot know the nature of the relationship, let us be content to seek for some of its conditions."

The psychiatrist is a physician who should take his point of view in a field even broader than that of general medicine in its largest sense, and not within the narrow limits of any specialism which may seem to include the sphere of mental activities. He has to deal with the physical effects upon the individual of all the influences that act upon him in his environment, and that enter into him from without, or are engendered within, which make for the maintenance or impairment of his vital processes. Such physical influences contributing to conscious experience have their mental effects; the psychiatrist must not only seek to understand the physical changes and effects, but he must deal with the patient's consciousness of them and the more subtle influences that affect the subconscious mental life. The physician must study not alone the influence, upon the mind, of the body in health and disease, but also the external physical, social and moral conditions of the environment unfavorable to mental health and growth. It is in association with this broader view of general medicine that, with respect to mental disorder, he must seek explanation on the physical side of the organism, and turn to expert research for such aid as can be given him by the contributing sciences.

The field of the medical sciences is as wide as that of biology, which comprehends all the interdependent phenomena of mental and physical life; the abnormal must be referred to the normal. The first recourse of the psychiatrist is to physiology whose domain is the study of the forces or functions of living matter. There are no symptoms until there are deviations from normal function; without functional activity disease is impossible.⁸ On the side of normal life, living substance necessarily presents the conditions of structure, form and function; these conditions are primary and disease is not necessary to the existence of living substance. Here the general physician finds himself involved in the contention between the sciences of physiology and pathology; the psychiatrist needs first a normal standard in his knowledge of general physiology, and all that he can learn of mental physiology and its relations to its mechanism, structure and form. Psychology lays open to intimate study the facts of the mental life; on the anatomical side we can know little, and that little explains nothing of the relations between mind and body. It is at this point that the physician must choose his point of view and form his conceptions of fundamental principles. If these are true, they should fit all discovered facts, whether of function or structure, and will lead to advancement of his knowledge; if not true they lead to conflict and

confusion, and obstruct progress. It is necessary to examine the mutual relations of the biological sciences to know their relative value to psychiatry.

THE POSITION OF PATHOLOGY AND ITS INFLUENCE UPON MODERN PSYCHIATRY.

The science of pathology, with the justification of its brilliant achievements, holds itself to be fundamental to the medical sciences. Its elucidation of the phenomena of disease and its results puts it into inseparable relation with life. It claims that its conceptions comprehend all of biology, for on all sides it bears essential relations to the subsidiary biological sciences. Deviations from normal structure and composition of the body, and from the normal functions of its parts, are held to belong to pathology; in this view the study of structural variations in the evolutionary and the developmental processes, from the normal in primordial and embryonal forms, may explain inherited and congenital disease, and, as a part of pathology, throw light upon morphology. Physics and chemistry, as they underlie both function and structure, contribute to the explanation of pathological change, and the disorders of function caused by disease; and pathological physiology and chemistry, whose importance is now receiving growing recognition, are to be regarded as subsidiary to pathology and dependent upon it. In the sphere of general pathology, dealing with function, it finds its duty to be "to correlate symptoms with structural changes and trace the connection between them."

The science of pathology, presenting by its salient aspects such claims to the physician who seeks for light upon the problems of psychiatry, reveals a changing history. The leadership of the pathological-anatomical school in France passing over to Germany culminated in the "cellular pathology" of Virchow, this being founded upon the principle that the cell is the unit of structure and function and that all vital processes are to be referred to the activity of the cells of which the body is composed; they are the "factors of existence." This includes the phenomena of disease and all alterations of the organs and tissues, the principle being that whatever acts upon the cell from without produces a change, either chemical or physical, in the cell structure, and disease is constituted of such changes. These principles became the foundation of the "exact medicine" of the present day. Griesinger first established modern psychiatry upon the exact basis of scientific research and pathological principles, and through Meynert pathological-anatomical teachings were greatly advanced; following them it was in such an environment that the latest schools of psychiatry had their beginnings with an immediate inheritance of its morphological conceptions as the fundamental criteria of scientific truth. Such were the conditions of the inception of the current teachings, based upon a rigid morphology. The German schools of psychiatry became the centers of interest and influence, and their characteristics have already been noted. In the history of the

⁸ Cf. Orth, J.: Relation of Pathology to Other Sciences. *Am. Medicine*, vol. ix, 1905. "Where there is no functional activity and thus no deviation from normal function, there can be no disease." Published while this paper was in manuscript.

time from Virchow, Griesinger and Meynert to the present there have been momentous advances in the other biological sciences as well as in pathology and psychiatry. The two latter lines of research are being strongly influenced by the concurrent changes. There are some very recent and significant signs of changing views in psychiatry which possibly betoken the freeing of itself from the too rigid dominance of structural pathology.

THE SANITARY IMPORTANCE OF CLEAN MILK.*

BY CHARLES HARRINGTON, M.D.

Assistant Professor of Hygiene, Harvard Medical School, and Secretary of the State Board of Health of Massachusetts.

OF the many subjects which of late have engrossed the attention of sanitarians and economists, none surpasses in importance these two: the enormous mortality of infants below the age of one year and the progressively diminishing birth-rates obtaining among the intelligent and well-to-do classes everywhere. Both are established facts, as every vital-statistician will testify. Concerning the various sociologic conditions responsible for the latter alarming condition, I propose to enter upon no discussion. We must recognize that that which has not inaptly been termed "race suicide" is "a condition and not a theory," and we can hardly hope that either academic discussion or public exhortation will be productive of any change for the better, but there is one phase of the subject, which, except from sanitarians, receives far too little attention, and that is the importance of preserving the lives of the diminishing number of those that are born. It is all very well to urge the importance of bringing larger numbers of infants into the world, but what can it avail if, after they are born, they are permitted to die forthwith? How much more does it profit a community to add to its numbers a hundred infants and lose twenty of them through easily preventable causes alone, than to add ninety, one tenth less, and protect them from these same preventable causes of death? The statesman and economist urge the importance of large families; the sanitarian, while agreeing, suggests that we save the infant lives that now are sacrificed. He can but show the way and urge upon the body politic the necessity of its co-operation.

Infantile death-rates are expressed as the annual number of deaths under one year of age to each thousand births. In most countries these rates are appallingly large. For example, in Germany, according to Professor Dembar, of Hamburg, of about 2,000,000 infants born yearly, about 400,000, or one fifth, are lost in their first year—a rate for the whole empire of 200. In the month of October, 1901, no fewer than eight

German cities had an infantile death-rate of more than 333. In Munich, during the period 1871 to 1903, inclusive, the rate was never less than 293; once it reached 419, and the average was 324. In Alsace-Lorraine, the figures are far more creditable; in 1901, 172; in 1902, 179; but even these figures are far too high.

In England and Wales, according to the report of the Registrar-General for 1903, the infantile mortality, during the decennial period 1893-1902, averaged 152 for the whole country, but the rate for cities and towns was about twice that for the rural districts.

The report for 1901 gives it as 146, against 132 in 1903. There was an increase in the 76 great towns, although the climatic conditions of the summer did not favor any prolonged prevalence of the usual main cause of death; and, during the past summer, there was in London, at least, a greatly increased mortality, every hospital for children being filled to its utmost capacity and many cases being turned away.

In England, in the third quarter of a recent year, no fewer than 52,847 infants died, mainly in the great towns, in 33 of which the mortality rate was 275 against 225 for the country at large.

In Birmingham, according to Dr. J. Robertson, M. O. H., more than 3,000 infants under one year of age die annually, against 35 at each yearly period between five and twenty-five years, and while the general death-rate shows a steady decline, the infantile rate shows no improvement.

In our own country, it is possible to obtain but limited information concerning the extent to which infants are permitted to die off, because of the failure of all but nine states and the District of Columbia to provide for registration of the vital statistics. The registration area comprises the New England States, New York, New Jersey, Michigan, and the District of Columbia (Pennsylvania has recently joined). Outside of this area, however, many cities and towns maintain a statistical office of some sort, and their returns are therefore available.

According to the Twelfth Census, the District of Columbia had, in 1900, an infant mortality rate of 271.5. The highest rate obtaining among the nine registration states was that of Rhode Island, 197.9; next came Massachusetts with 177.8; then New Hampshire with 172; New Jersey with 167.4; New York with 159.8; Connecticut with 156.8; and the others with a comparatively small rate showing but not too high.

Among the registration cities and towns of the country, we see Charleston, S. C., with a rate of more than 400; 419.5. There were 8,000 rates exceeding 300. In Maine, 1 in 3,000; 333.3; Fall River, 304.7; 2 in 3,000; 200; Georgia, 1 in 4,000; 250; 1 in 3,000; 333.3. High rates between 250 and 300 were 2 in New Hampshire, 1 in Massachusetts, Lowell, 294, and 17 in the South. No fewer than 47 cities, between 200 and 250, and 4 of these are Massachusetts cities, Salem, 247.7; Lawrence, 246; New Bedford, 222.9; and Holyoke, 204.4. Of the 18 having rates of 175 to 200, 2 belong to

*Read at the Boston Medical Library Meeting, Dec. 20, 1905.

Massachusetts — Boston and Cambridge — and these almost belong in the group preceding, their rates being respectively 194.1 and 186.5. We have, then, in Massachusetts, 8 cities with this discreditable infant mortality rate, ranging from 186.5 to 304.7.

When we ask to what these high rates are due, it must be answered that the causes are many and varied; but there is one cause that stands out most prominently, and that is the substitution of artificial, or bottle, feeding for the natural process of suckling. This is not the time to consider the many other preventable and non-preventable causes of infantile mortality, and I will, therefore, confine myself to this single and most important one.

Wherever the connection between these enormous losses and the method of feeding is investigated, the result of the inquiry is the same, and is condemnatory of artificial feeding. From various reports of British medical officers of health recently submitted, the following figures are taken as indicative of what might be expected in the way of results wherever the subject may be investigated. In one district, of 2,860 infants, 1,960 were suckled and 840 were bottle-fed; and of the former, but 2 died of diarrheal disease, while of the latter, the number was 59. But for the beneficial influence of the natural method of feeding, the 1,960 should have shown, instead of a diarrheal mortality of 2, one of 138, reckoning from the rate obtaining among the 840 that were bottle-fed. Thus, the danger of death from diarrheal disease was 70 times as great among the bottle-fed. In another district, 96 infants died during seven weeks of the summer of 1905, and 75 of them died of diarrheal disease. Nearly every one of these was bottle-fed. In still another, of all the infants that died of diarrheal disease between the ages of six and twelve months, during an entire year, 89% were bottle-fed. And practically all reports in which infantile mortality is discussed mention improper feeding as the one great cause.

An investigation on a large scale was that of the methods followed in feeding the 4,075 infants that died in Munich during the year 1903. This revealed the fact that 3,395, or 83.3% of the number, were bottle-fed.

And now may be asked the question, — What is there about bottle-feeding that makes such a difference? Of minor importance is this fact: that cow's milk is different in character and composition from that of the mother; but of tremendous importance is this other: that ordinary market-milk is, almost everywhere, a polluted, dirty food.

Where does the dirt come from? And just what is meant by the expression "*dirty milk*"? Dirty milk is that which contains large numbers of bacteria due to disease or to lack of care in production, handling and storage at the farm, during transportation and in the home. The matters containing the seeding bacteria get into the milk at various stages, and nature attends to the proper rate of bacterial multiplication.

In the first place, testimony from all over the world, collected during the past few months, indicates that almost everywhere the great majority of cow-stables are kept in such a condition of filth as to be unfit places for the production of milk for human consumption. The premises are dirty; the cows, often diseased, are never cleaned; the milkers are dirty in person and slovenly in their ways; the milking pails and other vessels are not properly cleaned; the milk is not properly cooled, handled and stored, the water supply is quite likely to be of more than doubtful character and exposed to the possibility of contamination with the exciting causes of infective disease.

Under ordinary circumstances, pollution of milk begins before the operation of milking is fairly under way. If the pail is clean before the milker takes his seat, it does not long remain so, for almost at once, dirty hairs and particles of dry cow-dung become dislodged from the animal and drop into it; and they continue to fall during the entire process. A gram of cow-dung is not a very large amount so far as volume and weight go, but Warrington has calculated that, coming from a hay-fed cow, it will contain about 165,000,000 bacteria; and, therefore, a small fraction of a gram in a pail of milk will contribute a very respectable number of millions of bacteria as a starter. Under favoring conditions of temperature, no further additions would be required to make the milk a good vehicle for cholera infantum. But it does not get off so easily; there are many other possibilities between the cow and the consumer, and others in the home of the latter.

The householder in the city takes everything on faith. He knows nothing of the conditions at the farm or whether the cows are diseased; he knows nothing of the conditions obtaining during transportation; he does not see the disgusting tasting process to which the peddler subjects each can before its final acceptance — the lapping of stoppers, the dipping out with a spoon which passes from can to mouth and back to the next can, while the taster spits about him on all sides that which he has tasted; sometimes the hand itself is dipped into can after can and lapped by the expert in tasting.

The consumer does not see the process of dumping the milk into large receptacles, visited by swarms of dirty flies that have but just before been paying visits to all manner of vile refuse in the vicinity. If they fall in instead of merely tracking dirt in on their feet, so much larger a contribution do they make to the flora of the milk.

The consumer does not see the horse-stable in which the milk is put up for family trade and stored until the following morning, when it will be delivered so early as to satisfy the demand for milk right from the farm. If he buys it in a shop, he knows nothing of the manner in which it is stored and handled by the additional middleman.

All the customer knows, as a rule, is this: that

the milk is delivered at his house in nice glass bottles early in the morning. And he lets it go at that.

Concerning the exciting causes of the various diarrheal diseases common to bottle-fed infants, we have reason to believe that they are numerous. Among them is Klein's *B. enteritidis sporogenes*, which is not yielded by cow-dung, but is found in horse-dung, and is believed by many English authorities to play a great part in the pollution of milk in the home, being blown about in the air of cities and gaining access to milk exposed, as it often is, to the air. I can imagine I hear somebody saying, "That's a small danger. Our milk comes in bottles and goes right into the ice chest." But it is not a small danger; pollution of milk with horse manure is more than a possibility; it is more than probable; for, strange as it may seem, horse manure is very commonly used as a bedding material for cows, and right here in Massachusetts too. Thus, in many cases, the milk may receive from the body of the cow particles of two kinds of dung at the same time.

Another cause of cholera infantum lies in the streptococci and other organisms contained in the pus contributed to the milk of cows suffering with garget, which is the most common of cattle diseases. But this is by no means the only disturbance which is caused in the consumer of pus as a beverage, for numerous extensive outbreaks of septic sore throat in persons of all ages have been traced directly to gargety cows. Concerning other bacteria which cause these various forms of milk poisoning, no discussion is at present necessary.

From what has been said, it must not be inferred that dirty milk is a menace to the health of infants under one year of age alone. It is among those of that age that the death-rate is most appalling, but among children of all ages up to five years the number of deaths due to the same cause is inexcusable and criminal. Nor must it be inferred that those that escape death are wholly free from the deleterious effects of filth, for the child that recovers from cholera infantum may suffer permanent injury to its constitution in spite of recovery. And it is not alone in behalf of infants and children that the sanitarian pleads for a clean milk supply; the invalid and convalescent are also to be considered, and the strong and well besides. Dirty milk is responsible for more outbreaks of typhoid fever than is polluted water in a state, which, like Massachusetts, guards its water-sheds from infection. In this Commonwealth, within the past year, nearly every one of the outbreaks of that disease of sufficient magnitude to cause public concern have been traced to insanitary dairies, where pre-existing cases had occurred, the patients being cared for, perhaps, by those who handled the milk, or themselves doing the milking and handling before taking to their beds or after apparent recovery.

I have not thus far referred to the danger which recent governmental commissions have agreed attends the use of milk from tuberculous cows

In view of all the evidence adduced, it is clear that tuberculosis, especially of the digestive tract, can be, and is, transmitted by such milk, especially if the disease in the cow has become localized in the udder. And such milk, with its pus and bacilli, is certainly to be classed as dirty.

Against the production and sale of diseased and ordinarily dirty milk it appears to be difficult to arouse intelligent public interest. The death of a few children from diphtheria or scarlet fever causes grave apprehension in a public that views with apparent equanimity wholesale murder through a polluted milk supply and will not lift its hand nor loosen its pocket to encourage those whose clean product must compete in the market with that of the slovenly. Clean milk costs more to the producer than dirty milk, for it means increased care and greater outlay for help; but, as an intelligent milkman wrote me recently, the public seems to prefer milk, plus cow-dung at eight cents per quart, to clean milk, not so flavored, at nine cents.

It is a crime to add substances commonly classed as poisons to milk or other food, even though the amount added be incapable of causing any apparent disturbance of health, but it appears to be quite legitimate to add the generators of the far more potent bacterial poisons in manure and other filth.

It is not generally known, except among the farmers, that the Massachusetts State Board of Health has, during the past year, been conducting, through a skilled veterinarian, a systematic inspection of dairies, and bringing about much needed improvement in conditions. The movement has occasioned some opposition from those whose horizons are somewhat limited, and has evoked some sympathy for the farmer from many of those whose conservatism is averse to altering any existing condition. In a certain locality, which had been visited, the feeling against official supervision was so strong that the local health board, which was contemplating co-operation, requested me to make a public address on the subject in the town hall. In the interval between the acceptance of the invitation and the date fixed for the address, an outbreak of some forty odd cases of typhoid fever occurred and an appeal for an investigation of its cause was made. It was demonstrated at once that the outbreak was due to milk polluted at its source, and the address was listened to by an audience that had become converted from sullen opposition to enthusiastic appreciation of the efforts of the board. That and several other communities have now become converted, and it is hoped that this change of sentiment will spread to all parts of the Commonwealth.

What is the cure for dirty milk? Some say that, if we sterilize or pasteurize, all will be well. But why injure the biologic properties of milk by heating? Why permit the pollution of milk by excrement, then kill the bacteria by heat and swallow the mixture? Why not prevent rather than cure? Why drink fecal matter and pus, even though it be sterilized?

The remedy is simple. We should insist upon clean milk and be willing to pay for it; encourage the production of a sanitary supply and refuse to buy excrement and pus; buy of the man whose supply costs a cent or two more per quart to produce, and let the sloven learn that cleanliness is an asset and filth a heavy load to carry.

THE RESULTS OF OPERATION FOR THE REMOVAL OF CEREBRAL TUMORS.*

BY PHILIP COOMBS KNAPP, A.M., M.D., BOSTON.

Clinical Instructor in Diseases of the Nervous System, Harvard Medical School; Physician for Diseases of the Nervous System, Boston City Hospital.

MORE than a word of apology seems necessary for presenting for the fourth time so arid a subject as the statistics of operations for the removal of tumors of the brain, especially when the present statistics are far from complete and lead to no more hopeful conclusions than those I have formerly expressed.¹ When I presented, six years ago, a fairly complete collection of operative cases, 561 in number, it seemed probable that the number of recorded cases would soon become so great as to render it hardly worth while to undertake another complete collection, nor since then has any one done more than to collect the complete statistics of operations in a certain region, such as the cerebellum.²

I have been asked, however, to present as an appendix to the paper of Doctors Walton and Paul³ the statistics of a recent collection of 267 cases which have been published since my last article, and which I made last winter for another purpose. I may state that I made no attempt, on this occasion, to make any exhaustive collection of the cases reported since 1899, but I simply took the cases readily accessible in abstract in the *Jahresbericht der Neurologie*, the *Neurologisches Centralblatt*, the *Revue Neurologique*, and such other cases as fell in my way without special research.

In 1899⁴ I collected 24 cases of operation on tumors of the brain. In 1891⁵ I added 48 cases to these, making 72 cases, and in 1899 I collected 489 cases more. It has seemed to me that it might be of some advantage to compare these three groups with the present collection to see what progress we have made in the surgical treatment of brain tumor, as well as to present the general results drawn from the whole collection of 828 cases, 14 of which have not as yet been published. The accompanying tables (Table I and Table II) will show the results of these operations as reported in 1899, the results in the 267 cases collected since, and the total results in

the 828 cases. The subsequent tables (Tables III, IV, V and VI) show the mortality, the number of cases not benefited by operation, and the number of cases in which there was a failure to remove the tumor in each of the four groups of cases, — those collected in 1889, in 1891, in 1899 and 1905, — together with the total results in the 828 cases. The cases classed as not benefited are those in the two columns of the previous tables headed "Not improved" and "Died." The percentages are given, but it must be remembered that they are somewhat fallacious. A single case in 1889, when only twenty-four cases were recorded, of course counted for about 4%, but in 1899 a single case counted for about one fifth of 1%.

These tables show that with the later cases there has been a diminished mortality as a result of the operation, and a somewhat greater number of cases benefited. Much of this gain I believe to be due to the improved surgical technique, which I think is obvious to every one who has followed attentively the methods of operating upon the brain since the earlier operations in the eighties. This is still more striking if we compare the mortality from operations on tumors of the central convolutions in Table II, in the collection of 1899 and of 1905, where the mortality percentages are 27 and 4½ respectively. Since 1899 there seems to have been a relatively greater increase in operations on other parts of the cerebrum, and in these the operation seems more fatal than the operation on tumors of the central convolutions. It is not improbable, however, that this diminution in mortality is more apparent than real. There is certainly a lessened tendency to report cases where the tumor was not found or could not be removed, and also where a tumor was removed with fatal results, so that there is probably an undue prominence of successful cases among those reported.

The table showing the percentage of failures to remove the growth is less flattering to the neurologist than the previous tables to the surgeon. In spite of the roseate hopes that are so often expressed, the failures in diagnosis are still great, and the slight diminution shown in the figures for the last six years may perhaps be explained merely by the failure to report the unsuccessful cases, rather than by any advance in the accuracy of our diagnoses.

In spite of the number of cases said to have "recovered," a study of the recorded cases confirms me in the belief that most of these simply linger on for a time, paralytic, epileptic or blind, and that in many instances the growth reurs. The cases of actual recovery, that is, of complete restoration to health, are exceedingly few. We cannot excise a portion of the cerebrum without a permanent impairment of function to a greater or less degree, according to the location and extent of our interference. Moreover, the growth itself gives rise to various changes, either changes in the cells throughout the brain, with disappearance of the tangential fibres (Giannelli⁶), or such

* Read at the thirty-first annual meeting of the American Neurological Association at Philadelphia, June 2, 1905.

¹ Boston Medical and Surgical Journal, April 5, 12, 19, 1899.

² Starr's Collection, Journal of Nervous and Mental Disease, July, 1903, embraces only 365 cases. Frazier has collected 116 cerebellar cases, N. Y. Med. Jour., Feb. 11, 18, 1905. I have not made use of his statistics because, as my own collection is incomplete, I felt that it would make the cerebellar cases unduly prominent.

changes as softening, hemorrhage, encephalitis and the like (Sagui?), in the immediate vicinity of the growth. It is, of course, justifiable to operate in suitable cases with the probability of affording temporary relief, but the possibility of a complete cure is slight, and the optimistic views, or rather hopes, so often expressed as to the benefits of operation are hardly justifiable.

A word may be said as to the so-called palliative operation for the relief of pressure, which it is claimed will relieve headache and arrest the progress of optic neuritis. This is true for only about one half of the cases. In many cases the headache has persisted and the neuritis has gone on until the patient became blind, even after a good-sized hole had been made in the skull. Here is a section of the brain from a patient who had, when I first saw him, Jacksonian epilepsy, slight paresis, occasional slight headache and no optic neuritis. Nine months later he was trephined, a hole about 4 cm. in diameter being made in the skull. The growth, an endothelioma growing from the dura, was not removed on account of hemorrhage. A year later he had much severe headache. He had become blind and hemiplegic, and marked mental symptoms, hallucinations, delusions and violent actions, had developed. The toxic factor in the production of neuritis has long been recognized, and it is believed by many to be of importance in the production of headache, mental disturbances and other symptoms. Relief of pressure will, therefore, have little influence upon any symptoms of toxic origin.

As an appendix I would add that from a study of 104 autopsies of tumor of the brain, it has seemed to me that 4 were anatomically accessible and presented enough clinical symptoms to be successfully localized so as to come under the heading of cases definitely operable, as described by Drs. Walton and Paul. Brunniche⁴ has

recorded 6 cases out of 209 as definitely operable. The figures which I have given in previous studies were intentionally as liberal as could be made, and included all the "possibly operable" cases as well.

In the previous tables I included a number of cases which have come under my own observation or have been operated on at the Boston City Hospital, 17 in all, most of which have not been published.

TABLE V.—PERCENTAGES OF FAILURE TO FIND THE GROWTH.

| | 1889. | 1891. | 1899. | 1905. | Total. |
|------------------------|-------|-------|-------|-------|--------|
| Removed | 18 | 28 | 265 | 160 | 471 |
| Not removed | 10 | 115 | 59 | 189 | |
| Per cent failure | 2 | 26 | 30 | 27 | 29 |

This table reckons only the cases where there was a definite failure to find the growth at the seat of operation. Many of the so-called palliative operations may fairly be regarded as failures in diagnosis, and the cases where it was impossible to remove the growth when found also point to the limitations of the operation. Including all these, failures to remove the percentages differ, but show the same general trend, that there has been little if any real gain in the percentage of tumors actually found and removed.

TABLE VI.—PERCENTAGES OF FAILURE TO REMOVE.

| | 1889. | 1891. | 1899. | 1905. | Total. |
|------------------------|-------|-------|-------|-------|--------|
| Removed | 18 | 28 | 265 | 160 | 471 |
| Not removed | 25 | 40 | 224 | 107 | 357 |
| Per cent failure | 25 | 41 | 46 | 40 | 43 |

A REPORT OF TWO CASES OF ERYTHEMA MULTIFORME DESQUAMATIVUM, ONE OF THEM COMPLICATED BY A PURPURIC ERUPTION, WITH A DISCUSSION OF THE UNDERLYING CONSTITUTIONAL CONDITIONS.

BY PHILIP KING BROWN, M.D., SAN FRANCISCO.

CONSIDERABLE interest has been given by the numerous papers of Osler on the subject, to the conditions which underlie many of the obscure forms of erythema. Not enough cases have been collected to enable one to get much of importance out of a study of these underlying conditions, or of the symptoms common to a majority of the cases. Indeed, in the comparatively large number reported by Osler in five different papers, a summary of the conditions in which some form of erythema was a complication gives one chiefly the idea of how widespread and obscure the etiological factors may be which cause this trouble.

A review of Osler's 29 cases gives some very important information as to the etiology, course

and severity of the trouble, its many-sided manifestations and complications. Eighteen of his cases were males. The youngest was three years of age, 17 were fifteen or under. The oldest was fifty-seven. Twenty-two had purpuric skin lesions; 17 urticaria; 5 circumscribed edema; 14 the usual form of erythema; 25 had colic; 17 arthritis or arthritic pains; 15 vomiting; 15 hemorrhages from the mucous membranes; 15 albumin; 14 nephritis as a cause for the albumin; 14 fever; 5 diarrhea; 7 enlarged spleen, 2 had endocarditis; 1 doubtful endocarditis; 5 died of uremia as a result of the nephritis. The other deaths were due in one case to pericarditis and one to pneumonia during the third attack.

The other unusual complications were otitis media in 3 cases; bronchitis in 2; spasmodic croup from edema in 1; aphasia and hemiplegia in 1, and pneumonia, not fatal, in 2. It was impossible to measure the duration of the trouble in many of the cases, but it had occurred an almost countless number of times over a period of twenty-seven years in one patient of fifty-seven who finally died from hemorrhages in an attack. The shortest duration, in a female child of four, was three weeks. This case had purpura, urticaria and edema, fever with gastro-intestinal crises, albumin without nephritis, and arthritic pains.

Osler himself does not attempt any classification of the conditions which may bring about erythematous manifestations, nor does he associate any particular form of erythema with certain types of the underlying trouble. The commonness with which purpura, including *peliosis rheumatica*, circumscribed edema and urticaria, occurred in his cases, led him to question whether there was not a close affinity among these skin manifestations. He calls special attention to the substitution of these affections for each other in the same patient at different times.

I quote a statement made in one of his papers, because it seems to me that simplicity in classification is demanded in these obscure conditions, and because it has been my experience that these varying manifestations occur interchangeably as the result of the same systemic conditions. The special statement of Osler reads as follows:

"Henoch's purpura, characterized especially by gastro-intestinal crises, and Schönlein's *peliosis rheumatica* may be regarded as hemorrhagic types of exudative erythema."

Bearing out this same point, Thibierge, in his *Traité de Médecine*, vol. III, groups both purpuras and urticarias under erythemas. He describes three types of purpura, namely, rheumatic, infectious and the purpura hemorrhagica of Werlhof. Galloway described a case of profuse exudative erythema with purpuric lesions and enterocolitis, and refers to "the purpuric type of the exudative lesions of the skin." Laver reports a case of arthritis, edema and erythema exudativa purpurica with final sloughing of the affected areas.

Carter reports a case of hemorrhagic exudative erythema in which he describes the purpuric

eruption as identical with Henoch's purpura. The French school generally regard purpura as an erythematous manifestation, and particularly Brocq and Besnier, who have added much to French literature on the varying manifestations of this disorder. Dermatologists take exception to this classification, but it seems reasonable, and purpura occurs so commonly with other erythematous manifestations in rheumatic and certain grave infections, that I think it important to maintain the connection.

The two cases of scarlatiniform or desquamative erythema which are recorded here are interesting in connection with several points in Osler's reports:

1. One had gastro-intestinal crises, fever, joint, heart and kidney complications; the other had intestinal disturbance, fever, slight kidney disturbance, angio-neurotic edema, and purpura with hemorrhages from the mucous membranes.

2. None of Osler's cases had the scarlatiniform variety of erythema which seems usually not to be associated with as severe conditions as in these two cases.

3. Digestive manifestations preceded all the attacks in one case and preceded the single attack in the other.

The histories of the two cases are as follows:

CASE I. W. P., male, age six and one-half years. History of repeated attacks of endocarditis for the past two years, associated with sore throat and tonsillar disturbance. In one such attack, lasting three or four days, had one or two convulsions with temperature of 101°. History of irregular heart action in the father with some rheumatism. Mother has had growing pains. Has early sclerotic changes in the arteries. Maternal grandmother died of cerebral hemorrhage at fifty-six.

For six weeks following an attack of tonsillitis, patient had a daily temperature ranging from 1 to 2.5 above normal. It is extremely irregular, being often up in the morning and normal at night. Complained of headache on exertion during this time, looked pale and had disturbed appetite.

Heart action during most of this four years has been irregular in rhythm, and a systolic murmur, loudest at apex, has been constantly present.

For months at a time there has been a temperature range of 1° to 2° daily, with nothing but the heart condition to account for it.

Jan. 1, 1905. Patient seen Dec. 31, 1904, having had ten days of epigastric pain, cramp-like in character. A temperature this morning aroused the family. At 10 a.m., I found a diffuse, tiny, regular eruption all over the trunk, shoulders and thighs, which had not appeared on the face, neck, arms or legs. It was perfectly discrete. It had no crescentic appearance and consisted of tiny reddened areas, slightly raised in the center, each one about the size of a pin head. There was no pain anywhere. There had been slight throat symptoms forty-eight hours before, but there was no eruption on the cheeks or throat. No corvæ nor eye symptoms. The glands were slightly large everywhere. There was no evidence of any skin infection. The heart was more irregular than usual and the murmur louder.

Temperature was 99.5 the following day, and the eruption had covered the entire body and the face except about the mouth. Where the itching had

caused him to scratch it a good deal, it was diffusely red between the patches, looking more like scarlet fever. There was a shotty feel to the eruption on the trunk and extremities. The palms and soles were also affected.

Temperature that afternoon rose to 102°, but on the two or three days following, it was not higher than 101°, and at 3.30 Jan. 6, was only 1° up.

Jan. 6. Patient's temperature last evening was still up to 100°. Examination of the urine shows a little albumin and a few casts, possibly more than could be expected from the febrile condition. Examination this morning shows the rash still lingering all over the body, although the face is quite clear, except on the neck. There are marks of his having scratched it very thoroughly in various places. The glands are easily felt all over the body, particularly the epitrochlear and postcervical glands.

Jan. 10. Patient has had rheumatic pains and swelling in the ankle joints of both feet for three days. The right ankle is still puffy this morning. Temperature ranges about 100°. He is peeling very markedly all over the scalp, and less markedly over the entire body, the peeling being scarcely perceptible as yet on the legs and the palmar surfaces of hands and feet. The peeling began Jan. 8, very lightly.

May 6. Boy's desquamation was complete six weeks after the attack was over. His nails desquamated but did not come off entirely.

The diagnosis of German measles was held for a day and scarlet fever was considered on account of the throat, but no report of the case was made to the health authorities. After the fourth day, desquamative erythema was diagnosed and some days later Dr. F. S. Burrows concurred in this. The throat condition was not more than a slight redness, with soreness on swallowing.

CASE II. M. C., male, age six and one-half years. Seen Jan. 8, 1904, 8 A.M., with Dr. K. Van Orden who gave the following history: Maternal grandmother had rheumatic joints. Paternal grandfather, now seventy-one, had rheumatic joints (ankles), one bad attack following overheating.

On the 7th of December, 1903, the patient was seen by Dr. Van Orden with a rheumatic attack. Temperature 101°. For several days had had pains in the back, arms and down the thighs. Felt cold and tired. On the 17th seen again with a temperature of 101° to 102°. Rash on the third day on the trunk; diagnosed German measles, mild attack. No cough, no sore throat. Seen only four days. On the 27th of December, day following a drive, had chilly sensation and temperature. Chilliness had been felt off and on for some weeks back. On the 28th a rash again appeared, brighter than before but of same character, spreading farther down the legs to toes. Very little on neck, none on face. Had been taking anisated ammonia, etc., little calomel, no quinine. The temperature reached 103° one day. Rash faded by the 30th. On the 31st rash gone and temperature normal. No desquamation. Not seen until Jan. 4. Had been up a day or two on limited diet. On evening of the 4th was downstairs. Felt badly all day. On the 5th complained of feeling cold, eyes heavy. On the 6th had fever of 104, flushed face, no vomiting, no sore throat. Was developing six-year old molars. On the 7th was more flushed on face, but not on body; hands and forearms to elbows and legs from toes to knees showed a papular vesicular eruption. Temperature 101-104.2°. Pulse 120 to 130. This eruption was noted in morning and didn't spread. On the 8th the face was edematous and there was a flush all over the body. Prepuce edematous. Complained of throat and eyes. Some ecchymoses on right shoulder. Tonsils said to be large. No

cough. Said to have passed some mucus with the stools yesterday. The urine was diminished this morning, but 26 oz. had been passed during the afternoon and early evening.

Examination: The child at 8 A.M., had a temperature of 101.5°. He was very bright. The face was considerably swollen and the eyes about half closed. There was no eruption on the face at all, but marked pallor. The papillae on the tongue were prominent and the tongue itself coated. The tonsils slightly large and red, with no membrane. There was no tenderness behind the ears, but the glands in the neck were slightly enlarged. The axillary and inguinal glands were tender and markedly enlarged, some of them being as large as very large beans. There was some swelling of the tissue under the angle of the right side of the jaw. There were some mottled red blotches, one nearly 1 cm. broad, on both ears. Over the chest and particularly over the back there was a slightly mottled but diffuse blush. It was particularly marked over the neck and buttocks, around the genital organs and slightly down the inner side of the thighs. Toward the extremities it became much more mottled, certain of the blotches being quite discrete. On the dependent parts the pressure of the clothes in folds had caused linear ecchymoses, looking very much like long scratches, particularly marked over the buttocks and shoulders. There was a marked absence of eruption or blush in the axillary spaces. The whole thing is said to have faded very much to-day. There is a slight puffiness over both ankles and the mother thinks over the instep. The conjunctivae of both lids are slightly reddened. No discharge from the nose. Spleen slightly enlarged. No abdominal tenderness. The heart sounds are not quite clear, the first sound being replaced by what is apparently a functional murmur, transmitted well to the neck. The breathing is slightly harsh over most of the left lung, but this is not noted with expiration.

Jan. 19, 9 A.M. Following the last note the eruption spread over the legs and became scarlatiniform in character. There still continued some swelling in the neck and the enlargement of the axillary and inguinal glands continued about the same. On the 14th multiple subcutaneous hemorrhages appeared on the chest and tongue. These grew worse through Saturday the 16th. That night the temperature was 101° and the patient had a nose bleed from one nostril which lasted nearly all night. The subcutaneous hemorrhages were none of them large. Most of them pin head in size. The largest the size of a split pea. The skin had been dry and had cracked and itched extremely, and he had scratched it quite vigorously for some days before the hemorrhages appeared. The urine continued clear and the heart action favorable through Saturday night. With the rise in temperature there was an increase in the heart activity and the boy complained of feeling cold in his back. The face became more and more swollen and the hands also quite edematous. The skin cracked at the angle of the eyes and at the mouth. On the 17th, the temperature reached 103°. On the 18th a pericardial rub was heard toward the base of the heart which had not been there the evening before. The skin has been irregularly desquamating for five or six days over the entire body. There have been no throat, ear or gastro-intestinal symptoms. There may be a slight amount of constipation, but the patient is largely on a milk diet. The hemorrhage from the nose was so profuse that a large quantity of clots were expectorated and the patient became excessively anemic.

Examination: Very faint pericardial friction is heard and a blowing systolic murmur. The heart

action is 120. The murmur undoubtedly hemic. Heavy black scabs all over the angles of the eyes and the mouth. Skin peeling everywhere. Skin very dry and pretty well covered with very faint tiny purplish spots which are not nearly faded out. The largest one is on the lower lip. There are a few millet seed in size over the point and under surfaces of the tongue. The spleen is not enlarged nor tender. The glands are everywhere enlarged to about the same size as noted before. The hands and feet are pale and slightly edematous. The edema in the face and neck are said to have disappeared practically in the last twenty-four hours. The scrotum and foreskin are not edematous. There is no tenderness anywhere except over the enlarged glands. No pains in the bones. Child's temperature this morning is normal.

The blood cultures taken Jan. 19 were negative. The blood examination showed 28% hemoglobin, 1,700,000 red cells, 6,800 whites. Differential, 41.5% polymorphs, 17.5% large lymphocytes, 36% small lymphocytes, 4.5% eosinophils, 5% myelocytes. The urine contained a faint trace of albumin with a few hyaline casts and a few leucocytes and red blood cells.

Jan. 20. The child has had an increased temperature of only about 1° by axilla for two days. The pulse runs 120 to 130. Skin is desquamating irregularly all over, more markedly on the backs of the hands. The fresh skin on the chest is slightly reddened and shiny, particularly on the lower border of the ribs. The papillae of the tongue are much enlarged, pale, glistening and with a pedunculated beaded appearance. The ends of the fingers are pale and brawny. Large purplish area of subcutaneous hemorrhage in the palms of both hands, particularly the left, nearly the size of a dollar. The purpuric eruption has almost faded and there are no fresh hemorrhages anywhere. The back of the left hand is more edematous than yesterday. The edema elsewhere is about the same. There is still a slight pericardial friction sound, but the hemic murmur is less marked than yesterday. The child is markedly constipated. Has no pains anywhere. Appetite is normal. Child has had Crede ointment on lower limbs for the last twenty-four hours, and is getting calcium chloride in 4-dram doses by rectum every six hours. Iron and arsenic internally.

Temperature remained normal. There was some little trouble in having the bowels moved satisfactorily; except for this no complication whatever occurred during his rapid convalescence. At this time he has about finished desquamating and his general condition has improved very rapidly. The heart trouble subsided at once although the heart is above 100 most of the time and when it is a little more rapid there is 1° of temperature.

Nov. 21, 1904. Father reports that the boy had a similar attack to the last one, only not nearly as severe, a few weeks ago. He was up in the country at the time. Had fever, a general eruption and later the skin peeled.

May 6, 1905. On examination yesterday, has three distinct ridges on the nails marked by a roughness and depression. He has had three attacks since the one that I saw him in. The first one last November a duplicate of the severe attack except for the hemorrhages and purpura. These attacks seem to have been preceded by an intestinal disturbance. For that reason he was kept six months on a diet of milk. In spite of the diet has had two more lighter attacks.

In August, 1905, he had a slight attack with temperature for two days preceded by a bad breath, but no distinct stomach attack. Eruption showed especially on hands and face both of which peeled.

There can be no doubt in the second case that all of the attacks were due to the same condition and were more or less severe manifestations of the same trouble. An interesting factor in both cases was the involvement of the heart. In two of Osler's cases were there endocardial complications and a third one died of pericarditis. In one of my cases there was a history of recurrent endocarditis with an involvement of the endocardium in the present attack, and in the other there was a pericarditis. Both boys, who were nearly the same age, had pain in the abdominal region. Both had also vague rheumatic histories. One had a history of pain in the back, arms and down the thighs, with temperature, a month before the attack. The other had had several attacks of tonsillitis and pains described as growing pains for several years. There was also a distinct rheumatic history in both parents of this child.

Erythematous, as manifestations of serious constitutional conditions, have been reported sporadically for many years. In general the underlying conditions may be classed as (a) serious disturbance of nutrition, (b) certain contagious diseases, (c) protozoan infections, (d) evidences of visceral disorders producing toxins as a result either of improper food or imperfect digestion and metabolism, (e) Bright's disease, (f) rheumatism.

As types of the nutritional causes, Galloway reports erythema induratum with focal necrosis and acute gangrene of half the trunk preceding death. Patient had grown suddenly very stout in the midst of the disorder. Mackenzie, in a discussion of erythemas, recalls a case of a youth unusually fat, with congestion of the cutaneous circulation. After several years of suffering with simple erythema, he developed exfoliative dermatitis, became emaciated and died.

Under the bacterial and protozoan causes are most of the severe contagious and infectious diseases,—typhoid, cholera, cerebrospinal meningitis, diphtheria, etc. Vaccination itself has been followed by various manifestations of erythema. Malaria has occasionally been accompanied by herpes, urticaria, petechial eruptions and even multiple gangrene. No characteristic form of the erythema has been constantly associated with severe malarial infections. Manson and Daniels report that trypanosoma infection causes erythema.

Most authors agree that erythematous manifestations occur most often in gastro-intestinal intoxications, from poisons introduced into the stomach, or from errors in metabolism. A great variety of types of erythema are reported under this heading, and the literature on the subject increases the list of substances classed under poisons all the time. Quite recently the various antitoxins have been added to the already long list. Diphtheria antitoxin was added to the list from the date of its first use.

The cases with eruptions and gastro-intestinal crises are, as a rule, the least serious form of the trouble, unless other complications supervene, as they are likely to in case the attacks recur.

Among the conditions underlying erythema and impossible of classification or belonging to the rheumatic class, Thornton has recently reported glandular fever associated with erythema nodosum.

McColluck reports a case of erythema nodosum and erythema multiforme coexisting in a boy of fifteen, subject to frequent attacks of tonsillitis, and in whom both types of erythema appeared at the same time. The process lasted about three weeks, the acute stage eight days. The family history was distinctly interesting. The mother had had erythema nodosum before marriage. Maternal grandmother had had rheumatic fever; an elder sister died at sixteen with endocarditis and multiple joint affections. A younger sister had had rheumatic fever with endocarditis, another sister repeated attacks of tonsillitis, and a maternal uncle and three children had rheumatic fever.

Carter described purpuric exudative erythema in a woman of twenty-nine without rheumatic, digestive, or hemophilic disorders prior to the onset of the trouble. The history is briefly as follows:

Twenty-four hours after a late supper of sweet-breads and coffee she had sore throat and eruption of bright red spots on both elbows, which spread next day to other parts of the body. With this were severe pains in the upper abdomen, controlled only with morphine. The joints were generally tender, but none were swollen or red. Excessive indican in urine at beginning of attack only. Two recurrences within three weeks. No kidney involvement. No leucocytosis. No temperature. Always undigested food in stools after a recurrence. Abdominal pain limited to upper abdomen and tenderness especially to stomach.

Hobfield reports multiform exudative erythema, erythema nodosum, rheumatism, chorea, endo- and peri-carditis in a nine-year old boy, with no etiologic factors, no unusual family history. A dilated stomach and gastro-intestinal catarrh were found at autopsy and a definite statement was made that there were no gastro-intestinal symptoms with or preceding the attack.

These cases represent the most usual conditions that occur in the severe forms of the disease and the commonest general manifestations of the trouble. The scarlatiniform variety may occur as a sequence of any of the conditions that bring about the other varieties, but idiopathic cases of the disease are noted.

Millard reports a case which he describes as erythema scarlatiniforme desquamativum in a man who had had yearly attacks since childhood and in whom he states there was distinctly no etiologic factors. The case is given briefly because of its similarity to one of my cases.

Man, thirty-six, afflicted with eruptions covering him from head to foot in two days "closely resembling a severe case of scarlet fever," but with slight pyrexia and spreading more rapidly than scarlet fever. Desquamation in sheets, soles and palms last, lasting three weeks.

Urine normal. No sore throat, no strawberry tongue. Patient had had similar attacks about once a year, irrespective of season, since a child. Once two attacks in three months. Nails shed once. No dietary errors. Eight brothers and sisters, all healthy, but two cousins had had similar but less severe attacks.

It is interesting in connection with one of my cases that all of the child's subsequent attacks, of which there have been eight or ten, were preceded by a slight temperature and bad breath, and the first movements after the attacks have been noted to contain undigested food. It will not do to place too much importance upon this observation, because an infection of any kind might interrupt digestion and cause gastro-intestinal manifestations. It would be impossible to state in such a case what the primary trouble really was.

The particular type of the disease illustrated by Millard's case as well as my two cases has occasionally been considered an idiopathic condition. Its independent existence, however, may be set aside, since it has been shown repeatedly by French writers, in whose country the disorder seems commoner than anywhere else, to be a symptom of some general disorder. Furthermore, v. Duhring of Constantinople has recently reported an epidemic of this form of erythema. The French authors regard the desquamative form as a sub-acute condition, occasionally so obscure in its etiological relations as to make its cause impossible to ascertain. It has resulted from as slight a condition as drug poison and it has complicated a good many of the infectious diseases of childhood.

Its similarity to scarlet fever is beautifully illustrated by both of my cases but more particularly the milder one. The rash was practically indistinguishable from scarlet fever and desquamation took place from the hair to the soles of the feet. The tongue especially was quite typical. Cases are reported where the recurrences are more frequent than they were in my second case, complete desquamation taking place each time, the intervals between the attacks being so short that the skin in some parts of the body was constantly in a state of exfoliation. This condition resembles closely the exfoliative type of dermatitis, which is not infrequently the terminal condition in this peculiar disorder. What helps further to distinguish it from scarlet fever is its earlier period of desquamation, the rather striking absence of throat symptoms in a majority of cases, its recurrence, the absence of the peculiar pale ring about the mouth and a disproportion between the fever and the intensity of eruption.

Reports of Societies.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.
 THIRTY-FIRST ANNUAL MEETING HELD AT INDIAN-
 APOLIS, IND., OCT. 10, 11 AND 12, 1905.

SURGICAL SECTION.

(Concluded from No. 4, p. 110.)

INTRAPERITONEAL TUBERCULOSIS.

DR. F. F. LAWRENCE, of Columbus, Ohio, read a paper on this subject in which he drew the following conclusions: "1. Intraperitoneal tuberculosis is frequently a local disease. 2. It probably occurs much more frequently in the female than in the male. 3. In a large majority of cases it is primarily visceral and the general peritoneum is secondarily involved. 4. The surgical treatment is rational, sometimes agreeably surprising in results, and again bitterly disappointing. 5. In this, as in many other surgical conditions, early diagnosis and early operation will bring more certain results. 6. In this condition the greatest obstacle to overcome is the idea that it is a secondary condition. 7. No case of intraperitoneal tuberculosis should be denied the benefits of operation, no matter how extensive, so long as there is no positive pulmonary or pleuritic involvement, for the reason that some apparently hopeless cases fully recover. 8. When there is a tubercular peritonitis, a sequeal of tubercular tubes, ovaries or appendix, the primary focus should always be removed. 9. In these tubercular cases the mesenteric glands have not been found frequently involved, and when they are operation accomplishes very little good. 10. In tubercle of tubes and ovaries the adhesions are usually firm, sometimes, though not usually, very vascular and not infrequently involve loops of the small intestine; hence the greatest care is necessary to avoid serious injury to bowel and at the same time separate completely all adherent surfaces and provide complete drainage. 11. Drainage is the great factor in recovery, when properly carried out."

PYLOREPLASTY WITH THE MCGRAW LIGATURE.

DR. J. HENRY CARSTENS, of Detroit, Mich., said that many cases with disturbances of indigestion could not be diagnosed or relieved by medication. These should be subjected to an exploratory celiotomy. Gastro-enterologists should not treat patients for months and years if they could not make a positive diagnosis or cure the patient. After reasonable efforts the patient should be sent to the surgeon for relief. The McGraw ligature was a valuable means of relieving stricture at the pylorus and the resulting dilatation of the stomach. This method of operating was easy and quick, the danger was very small, and the operation was preferable to those heretofore used in benign contractions at the pylorus. It was a great deal better than gastro-enterostomy, as one restored as nearly as possible the normal condition. Quite a number of gastro-enterostomies had been reported, with a most gratifying result in some of the cases, but the difficulties

encountered, the trouble with the vicious circle, frequently called for a double operation. The McGraw elastic ligature method should be the operation of choice.

Dr. Carstens concluded by saying that: (1) Many stomach troubles were due to mechanical means. (2) These cases could only be relieved by surgery. (3) Many cases could not be properly diagnosed in the present state of our knowledge. (4) Obscure cases that had been subjected to various modes of treatment without benefit should receive the benefit of an exploratory celiotomy.

OVARIAN CYSTOMA.

DR. L. P. LUCKETT, of Terre Haute, Ind., reported a case of ovarian cystoma upon which he had operated. The tumor originated from the left ovary, was attached by a broad pedicle which was tied off in sections. The uterus and right ovary were found to be normal. The fluid and tumor were estimated to have weighed between seventy and eighty pounds. The patient made an excellent recovery.

SURGICAL TREATMENT OF NEPHRITIS.

DR. ALEXANDER HUGH FERGUSON, of Chicago, presented a further report on the surgical treatment of this disease. He reported seven cases upon which he had operated, with two deaths.

CASE I. Capsulectomy and nephrotomy; return of symptoms; no second operation; still improved.

CASE II. Chronic nephritis and pregnancy; unilateral capsulectomy and nephrotomy, with recovery.

CASE III. Chronic painful left interstitial nephritis, capsulectomy and nephrotomy, followed by recovery.

CASE IV. Nephritis; unilateral capsulectomy and nephrotomy, with recovery.

CASE V. Nephritis; unilateral capsulectomy and nephrotomy; death.

CASE VI. Bilateral nephritis; bilateral capsulectomy; unilateral nephrotomy; multiple punctures on the other side; death.

CASE VII. Double recapsulectomy; multiple punctures; patient progressing toward recovery.

DR. MAXWELL J. ROSENTHAL, of Fort Wayne, Ind., discussed the subject of

CLOSURE OF UTERO- AND VESIO-VAGINAL FISTULA.

and reported a case. The author concluded by saying that a considerable area of scar tissue and vaginal mucosa might be inverted into the bladder without producing ill effects. Uteral isthmus embedded in scar tissue might be inverted into the bladder and continue to discharge its urine without becoming stenosed. Even large vaginal fistulae, where part of the bladder walls were lost in scar tissue from a previous hysterectomy, might be successfully operated by the operation of denudation and closure through the vagina without disturbing the relations of the bladder or any adhesions of pelvic viscera which might have formed in the scar.

SPRAINED ANKLE.

DR. ROBERT CAROTHERS, of Cincinnati, Ohio, read a paper on this subject in which he drew the following conclusions: "1. No one is exempt from a sprained ankle although some are more prone to it than others."

2. That in severity, a sprained ankle will range from a trivial incident to one of extreme severity, which may last long. 3. That the outer side is more often than the inner side of the ankle is the seat of trouble. 4. That the diagnosis which is ordinarily made with ease is at times made with difficulty, and occasionally a very examination is required to make the diagnosis certain.

(5) That the treatment by immobilization with a plaster-of-Paris cast is unsatisfactory and at times injurious. (6) That the treatment instituted by Cotteral, the so-called adhesive plaster strappings, advising and urging the patient to walk on the injured foot, the early removal of these straps, followed by massage, gives the most satisfactory and best results. (7) That the old cases are to be, under anesthesia, converted into acute sprains and treated in the same manner.

DR. DAVID C. PEYTON, of Jeffersonville, Ind., reported an interesting case of pyemia following an operation for appendicitis.

APPENDICITIS.

DR. R. E. HAUGHTON, of Richmond, Ind., followed with a paper on the history, differential diagnosis, pathology and etiology, medical and surgical treatment, of this disease. He presented a brief history and plea for an abatement of the use of the knife in place of treatment by remedies, in view of the statistics and results.

SHALL THE PROFESSION OR THE LAITY BE RESPONSIBLE FOR THE DEATH-RATE IN APPENDICITIS?

DR. J. C. O'DAY, of Oil City, Pa., said that every physician, when confronted with a case of appendicitis, should frankly tell the patient the nature of his trouble; explain to him, honestly and candidly, the disposition of his disease; that no one could tell what an inflamed appendix would do, and that there was no safety till the offending organ had been removed. If the patient then decided to defer operation, he, not the surgeon, should be responsible. If it were done, he thought we would hear no more complaints of, Why did not the physician advise operation before it was too late?

SARCOMA OF THE ANTERIOR SEGMENT OF THE GLOBE.

DR. O. TYDINGS, of Piqua, Ohio, presented a brief history of a patient upon whom he had operated for the removal of melano-sarcoma of the anterior segment of the globe. The diagnosis of melano-sarcoma was confirmed by competent pathologists. Five days after the removal of the tumor the patient dropped out of sight and the speaker did not see him again until the following August. There was no recurrence; the cicatrix was smooth; the lone pigmented spot, not larger than a pin-point, which the author took to be the remains of an old hernia of the iris, was still present, but absolutely quiescent. The patient's vision which, when he first saw him, was right eye, 20-40, and when operated 20-200; left 20-30, was now 20-20 in each eye. So far as the author had been able to examine authorities, the case stood alone. Primary melano-sarcoma of the cornea is rare. Nine cases had been reported of sarcoma of the cornea by different authorities. None of these cases, however, according to an English authority, was above suspicion.

THREE CASES OF EXTRAPERITONEAL RUPTURE OF THE BLADDER COMPLICATING FRACTURE OF THE PELVIS, WITH RECOVERY.

DR. JOSEPH RILUS EASTMAN, of Indianapolis, said that injuries of the pelvic bones were attended with more or less risk to life which did not ensue solely from the damage done to the bones themselves, but arose usually from the injuries done to the viscera of the region involved. Formerly, death occurred in a large percentage of cases of rupture of the bladder.

The mortality was naturally much higher in those cases in which a tear of the peritoneum made possible

the entrance of urine into the peritoneal cavity. However, extravasation of urine through the pelvic connective tissue in cases of purely extraperitoneal bladder rupture also formerly caused a high mortality rate. This mortality rate had been decidedly decreased by modern methods of dealing with shock, and free and rational bladder drainage. The immediate and characteristic symptoms of the injury were intense pain in the abdomen, collapse, and great irritation of the urinary reflex, with ineffectual attempts to void urine. Inability to void the urine was usually present, whether the peritoneum was torn or not. If the peritoneum was injured, peritonitis of the sthenic type developed duly. As the injury usually occurred while the bladder was full, an area of dullness and tenderness was to be found over the bladder, extending irregularly beyond the normal limitations of bladder dullness, and a large amount of bloody urine might usually be withdrawn by catheterization.

As to the diagnosis of fracture of the pelvis itself, this could occasionally be made visually. Usually, however, the surgeon must depend upon his senses of sight, touch and hearing for the well-known signs of fracture, deformity, abnormal mobility and crepitation. The deformity was usually not pronounced.

In the three cases described by the author, the treatment consisted in combating shock, chiefly with normal salt solution and adrenalin, in the removal of clot, suture of the rent in the bladder, appropriate bladder drainage, rest and the application of a bandage in such a manner as to prevent movement of the pieces of bone which were broken off.

The following papers were also read: "Note on Bone Tuberculosis, with Report of a Case," by Dr. W. W. Vinnedge, Lafayette, Ind.; "Post-Operative Acute Dilatation of the Stomach, with Report of a Case following Nephroproxy," by Dr. A. E. Halstead, Chicago; "Treatment of Tuberculosis of the Cervical Lymphatics," by Dr. H. C. Sharp, Jeffersonville, Ind.; "Visceral Ptosis; Its Surgery," by Dr. Earl Harlan, Cincinnati, Ohio; "The After-Treatment of Gastroenterostomy," by Dr. Charles A. L. Reed, Cincinnati, Ohio; "Cysts of the Mesentery, with Report of a Case," by Dr. L. G. Bowers, Dayton, Ohio; "Perforating Ulcers of the Duodenum, with Report of a Case," by Dr. M. A. Austin, Anderson, Ind.

The following preamble and resolution were unanimously adopted by the Section:

WHEREAS, the medical profession keenly realizes the great and increasing public evil, moral, mental and physical, arising out of the support given by the public press to the so-called patent medicine interests, leading to the pernicious practices of self-drugging, narcotic habituation and alcoholic excess; be it

Resolved, That the Mississippi Valley Medical Association commends and frankly endorses the attitude adopted by *Collier's Weekly* and the *Ladies' Home Journal* in giving publicity in the articles by Samuel Hopkins Adams, Norman Hapgood and Edward Bok, respectively, to the truthful exposure of the nefarious practices and unscrupulous methods of the so-called patent medicine concerns."

OFFICERS.

The following officers were elected for the ensuing year: President, Dr. J. Henry Carstens, Detroit, Mich.; First Vice-President, Dr. Joseph Rilus Eastman, Indianapolis, Ind.; Second Vice-President, Dr. H. H. Grant, Louisville, Ky.; Secretary, Dr. Henry Enos Tuley, Louisville, Ky., re-elected; Treasurer, Dr. S. C. Stanton, Chicago, re-elected.

Hot Springs, Ark., was selected as the place for holding the next annual meeting.

MEDICAL SECTION.

WHAT IS THE PRESENT CONCEPTION OF BRIGHT'S DISEASE?

DR. G. W. McCASKEY, of Fort Wayne, Ind., read a paper on this subject, in which he said that the only possible justification for the use of the term was an historical one, and while its meaning must in a sense change with the changing views of pathology, yet the primary groundwork which constituted the historical basis on which it stood should be kept constantly in view. He presented a brief inquiry as to the character of the group of morbid states and symptoms originally described by Bright. The investigations of Gull and Sutton on the relation of arterio-capillary fibrosis as a cause of contracted kidney were the most important steps in broadening the views entertained concerning Bright's disease. They demonstrated the systemic or hematogenous character of one clinical type of the disease, which naturally stimulated thought and investigation with reference to other types along the same line. In spite of the advances in pathological doctrine, in spite of the mutations of opinion and classification, one could not but be impressed by the close resemblance between the views entertained to-day and those of half a century ago concerning what might be called the gross features of Bright's disease.

For the purpose of a broad general view of the subject, the author divided the causal conditions into six classes: (1) The acute infections; (2) Chronic infections; (3) Chemical poisons introduced into the circulation, of which lead may be taken as a type; (4) The influence of cold; (5) The products of perverted gastro-intestinal function, and especially intestinal putrefaction; and (6) The products of perverted metabolism.

THE COMBINED METHOD OF TREATMENT IN THE ARREST AND CURE OF TUBERCULOSIS.

DR. H. B. WEAVER, of Asheville, N. C., stated, among other things, that in order to wage a successful warfare against tuberculosis and prevent its spread, the method which was pointed out by nature consisted in increasing as far as possible the organism. All efforts, therefore, should be directed toward that goal. As only two per cent of tuberculous patients were treated in sanatoria, that method could not now bring the desired relief. Ninety-eight per cent of patients were treated in their homes. Therefore, the general practitioner, as remarked by Osler, was, after all, the man behind the gun in this warfare, and to him, and through him, we must look for ultimate success. Tuberculosis would only then be vanquished, when it shall have become possible to strengthen the organism and assist with specific powers which will render it immune against the disease.

THE TREATMENT OF TUBERCULOUS PLEURISY WITH EFFUSION.

DR. THEODORE POTTER, of Indianapolis, Ind., submitted for consideration the following propositions: (1) That the profession had gone too far in accepting the general principle and following the general practice that pleural serous effusions, unless they showed a tendency to early absorption, should be removed. (2) Granting that in the majority of such cases pleurisy was the dominant feature and removal of the fluid the proper procedure, and that such removal would probably tend to arrest the pleural tuberculosis, which was usually present, nevertheless, the best results ought to be obtained by dealing with each case upon its own merits. (3) In cases in which the pleurisy was the sole or dominant feature, the removal of the fluid was

the proper treatment; and in proportion to the accuracy of differentiation between the pleural and the pulmonary disease would be the promise of good results by removal of an effusion. (4) In cases in which tuberculosis of the lung was evidently or probably the overshadowing feature, a conservative course as regards the removal of a serous effusion was the proper one. In some cases the fluid had best be left to nature to take care of, with the hope that the compression, immobilization and physiological quietude of the tuberculous lung might tend to arrest the disease. In other cases of this type the removal of the fluid should be undertaken only upon a deliberate judgment, after due consideration.

TUBERCULOSIS IN GENERAL PRACTICE.

DR. HUGH A. COWING, of Muncie, Ind., said that in his relation to tuberculosis the general practitioner should exercise great care in physical examination. He should strive to make an early diagnosis. He should carry a life-saving knowledge into the tuberculous home, improve its hygiene and teach sanitation. He should employ the pure air treatment. The method would vary to suit the individual case and condition. He should co-operate with health boards, and report cases. He should count the cost before sending the patient to a health resort. He should study health resorts and sanatoriums, and visit them, if possible. He should oppose quack consumption cures and quack doctors who "cure consumption." He should influence the press for sanitation. He should fight patent medicines. He should expose Christian Science, and kindred fads that rob the consumptive of his chance for life. He should endeavor to seek legislation for sanitary advancement. He should help to popularize the consumptive sanatorium and health farm. Membership in a society for the prevention of tuberculosis would make the physician's work more effective.

THE MANAGEMENT OF NEURASTHENICS.

DR. H. A. RODENBACH, of Columbus, Ohio, said that an individual became neurasthenic only after having suffered from some of the psycho-neuroses, the latter having been caused by traumatism, by disturbed metabolism, or by peripheral nerve irritation. Heredity, occupation or environment could hardly be considered etiological factors without further specification. Neurasthenia should be considered a mental rather than a physical disease. Mental symptoms often persisted after removal of all physical causes, and could only be relieved by psychic treatment. Mental hygiene was both preventive and curative. The neurasthenic should be taught that a healthy mental attitude conduced to bodily health.

AUTO-INTOXICATION.

DR. D. L. FIELD, of Jeffersonville, Ind., read a paper on this subject. After referring to the theories and definitions of auto-intoxication by Bouchard and others, the author said that the part played by the intestinal emunctories in the elimination of certain poisonous substances was attested by the commonly fetid stools of persons who frequented post-mortems. The fetid character recalled the putrid odor of the emanations from the cadaver.

If poisonous products had been absorbed, an effort should be made to destroy them. The liver had the power of arresting poisons. It withdrew them from the intestines and eliminated destroyed them. One should, therefore, stimulate its action by proper therapeutic measures. If the poisons had escaped the liver, they should be eliminated by the skin, the lungs,

the intestines and the kidneys. If all these attempts failed, one should have recourse to certain antidotes which tended to counteract the physiological effects of the poisons which menaced the system. As a striking example he mentioned the antagonistic properties of poisons in atropine and pilocarpine. The strength of the patient should not be neglected, so that he might have time to eliminate the poisons. Sometimes it was only necessary to keep a patient alive a few minutes more in order to save him. We could not provide him with radical force, and what was required was active force. Thus one was led to administer stimulants which might awaken the forces remaining latent. Cases were cited in point.

SOME REMARKS ON THE PATHOLOGY OF EPILEPSY.

DR. MARC RAY HUGHES, of St. Louis, Mo., showed that each epileptic stage had a distinct pathology, and the entire category for classification of epilepsy, including the psychical varieties, had one common pathology or gross structural change, and that this structural change, whether idiopathic or organic, had to do largely with the movements of the centrifugal and centripetal mental forces as they were found in the psychical equivalent of epilepsy, — dual consciousness, obliviousness and allied states of mental eclampsia.

HISTORY AND TREATMENT OF EPILEPSY.

DR. JOHN W. SELMAN, of Greenfield, Ind., after recounting at length the history of this disease, said that every physician acknowledged that the great cause of epileptic convulsions was the sudden liberation or explosion of nerve force which swept everything before it. Epilepsy and other diseases might exist together, and for this reason the prognosis diagnosis were to be carefully formed and given.

Jan. 2, 1905, a man, twenty-eight years old, was brought to him, who was having epileptic seizures five and six times a week. There was no aura. Like a flash he was in hard convulsions. The general appearance of the patient indicated great anemia, malnutrition, with diarrhea. The author at once used subcutaneous injections of normal saline solution, with the bitter tonics and arsenic, and at the expiration of ten days a great change in his condition was noticeable, and in three months he returned home apparently well.

The causes of epilepsy were toxic, reflex and traumatic.

The treatment of the disease was as various as the disease was variable in its forms and phases, and it should in nearly all cases resolve itself into three divisions, consisting in the removal of any exciting cause, in the checking of the convulsive tendency already set up, and in the prevention of any further attacks by suitable drugs or other measures of relief. The treatment was governed largely by the case and was medicinal or operative, according to the causal factors at work. In idiopathic epilepsy medicinal means should be followed; while in a case resulting from traumatism, the depressed bone, abscess or tumor should be removed.

THE CIGARETTE; ITS RELATION TO MENTAL AND NERVOUS DISEASES.

DR. W. B. FLETCHER, of Indianapolis, Ind., quoted extensively from articles by physicians and prominent laymen on the cigarette habit, and said that he had sometimes asked himself if the members of the medical profession were not largely responsible for the widespread prejudice against the cigarette. It was so much easier to agree with the grief-stricken

mother in assigning the cause of the loved one's downfall to the innocent habit of cigarette smoking than to say to her frankly the real cause which examination had revealed or which had been imparted under the seal of professional confidence. In the past twenty-two years he had examined over twelve hundred cases of nervous disease and insanity brought to the Central Hospital for the Insane, or in his private practice, where the cause of the malady was given by their friends as the cigarette habit. In not one case had he reason to believe that tobacco had anything to do with the causation of the disease. They were all young men and some of them insane without doubt. Some of them smoked cigarettes to excess, but their insanity was only a cause of their excess, and not the excess the cause of the insanity. Many of them were simple cases of hebephrenia, with a cigarette attachment, so to speak. One poor fellow, sixteen years of age, and at the time in acute mania, had been severely punished by his father to "beat out the cigarette habit." After three months he recovered and proved to be an unusually bright and truthful boy. He acknowledged that he had smoked three cigarettes in his life just before his mind gave way from overwork in the harvest field. Some of the cases were tuberculosis of the brain, but he thought he was safe in saying that fully ninety per cent were young fellows reared in idleness, who had acquired other habits of vulgar and vicious companions which were reducing their vitality and sapping their brain, and the cigarette was used as a cover by patient, parents and friends as a scapegoat, or an excuse to hide their shame.

A PLEA FOR MORE MORAL RESTRAINT FOR STUDENTS IN MEDICAL COLLEGES.

DR. JOHN M. BATTEN, of Downingtown, Pa., said there were three classes of students at medical colleges: First, those who had good morals, were industrious and ambitious, and had a high ideal objective point. Second, those whose morals were questionable, and were not as industrious as they should be, and were lacking in ambition, and consequently their ideal objective point was only mediocre. This class of students was easily led into evil habits. Third, there was a class of students who might have plenty of means furnished them for necessary and other expenses. Their ideal objective point in life was not high. Their morals were corrupt, and they had not been taught the value of economy. This class of students schemed to do evil and endeavored to corrupt others with whom they associated. He thought no medical college should have a charter that could not and would not provide for sufficient moral protection over the students who attended such institutions.

THE TONIC ALTERNATIVE ACTION OF COPPER AND ARSENIC IN PRIMARY AND SECONDARY SPANEMIC STATES.

DR. GEORGE F. BUTLER, of Chicago, said that arsenic had a very decided action on tissue change and markedly affected the glandular, nervous, respiratory and cutaneous systems. Copper was reputed to be a violent poison, yet, except so far as its toxic effects as a foreign body in the eye was concerned, this repute was decidedly undeserved. Copper was recommended as an alternative tonic useful in epilepsy, chorea and other spasmodic conditions, especially those connected with debility by the older authors, and later therapeutists sustained this old repute of copper. Several authorities were quoted to the effect that the drug, in small doses, stimulated both the heart and the capillary circulation, and was a general nerve tonic. As to the preparation to be employed, all agreed that while

copper sulphate was of value, it had at times unexpected, dangerous, untoward effects when the point of saturation was reached. These effects, through the influence of the drug on the vascular system, often took the direction of cardiac neuralgias and pseudo-anginas. The double salts of copper in small doses exerted a cardiac action similar to that of digitalin, strophanthus, helleborein, etc. Rare preferred copper arsenite. He had found that under its use digestion and nutrition improved. It was superior to Fowler's solution in chorea and similar neuroses. In toxic conditions, like secondary malarious manifestations with the resultant pallor, copper and arsenic were of decided value. Cases in which the periodic tendency had disappeared improved decidedly under copper and arsenic, whereas quinine and iron were worse than useless. The influence of arsenic was very marked on chronic rheumatism and so-called rheumatic gout, neuralgias of various sorts, in tic and hemiplegia, as well as in angina pectoris, chorea, epilepsy and asthma. In certain of the gouty bronchitides, at the onset of phthisis, in imperfectly cleared up pneumonic lung consolidation, arsenic acted sometimes with remarkable efficiency. The influence of both drugs on the liver, whose double functions were so necessary to the tissue changes of the system, showed that both played a part in assisting assimilation, and at the same time destroying waste products.

THE CLAIMS OF THE ADOLESCENT.

DR. FRANK P. NORRICKY, of Jacksonville, Ill., said that the claims of the adolescent for recognition by the medical profession were genuine, not hypothetical, and involved three important considerations: (1) Physiological — a study of growth, development, sex differentiation. (2) Psychological — normal and morbid, involving honest endeavor of the physician to see the real needs of the individual. (3) Pedagogical — training and treatment to go together.

All of these considerations showed that a demand existed for qualified men to consider earnestly the problems of mind and body of this period.

The following papers were likewise read: "Heads and Tales," by Dr. T. B. Grosvenor, of Meadow Lawn, Ky.; "Simple Eye Conditions that Should be Familiar to Every Physician," by Dr. Mark P. Stevenson, of Akron, Ohio; "Some Interesting Problems in Urinary Diagnosis," by Dr. Arthur R. Elliott, of Chicago; "Concerning Hepatic Uremia and its Treatment," by Dr. Alfred C. Croftan, of Chicago; "Enterotoxism (Auto-Intoxication) from Meat," by Dr. Fenton B. Turck, of Chicago; "The Leucocytes in Pertussis," by Dr. F. S. Churchill, of Chicago; "Remarks on Polymyelitis," by Dr. Hugh T. Patrick, of Chicago; "Demonstration of Sleep-Inducing Method," by Dr. J. B. Learned, of Northampton, Mass.; "Some Rare Sequels of Syphilis," by Dr. Henry J. Scherck, of St. Louis, Mo.

Recent Literature.

The Treatment of Fractures. By CHARLES LOCKY SCUDDER, M.D., Surgeon at the Massachusetts General Hospital. Fifth edition, thoroughly revised. Octavo, 563 pages, with 739 illustrations. Philadelphia and London: W. B. Saunders & Co. 1905.

Dr. Scudder's efforts to keep his work on Fractures up-to-date and its popularity are apparently the chief causes for the appearance of the

fifth edition of this work. Few medical books have met such a demand as to require five editions in as many years.

The "form" of the work, both as regards arrangement and subject matter, is essentially the same as in previous editions. As regards the illustrations, which are increased in number from 688 to 739, many "x-rays" are reproduced to illustrate the actual line of fracture. The volume, still an octavo, is enlarged from 531 to 563 pages by the additions to this edition. The author states that he has carefully revised the text and made such additions and changes as more extended experience indicated. He calls attention to the changes now taking place in the treatment of fractures of the hip which may possibly radically alter the treatment of this injury.

The chief characteristics of this book, as well as of its previous editions, are the graphic, precise manner of presenting the actual condition of the fractured bones by reproduction of x-ray plates and anatomical descriptions; the reproduction of photographs of the actual clinical lesion; and the attention to detail in description of treatment. In a large majority of instances the statements of the writer represent the best modern opinions and methods.

Points for criticism are not easily found. Among those noted are the wrong lettering of some of the muscles in the plates showing the pathological anatomy of the muscles in dislocation of the shoulder, which occurred also in the fourth edition, and is uncorrected in this, and that the article on dislocation of the hip is disproportionately short considering the importance of the lesion. It is very concisely written and without illustrations.

The bibliography appended is a valuable addition to the work and includes the titles of many noted monographs. As a whole, the book still stands as an exponent of the modern treatment of fractures.

The Thyroid and Parathyroid Glands. By HERMUT RICHMONDS, M.D., late Pathologist to Mount Hope Retreat; Pathologist to Maryland Asylum and Training School for Feeble-Minded Children; Demonstrator of Physiologic Chemistry, University of Maryland. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1905.

This book is a monograph on the subject of the thyroid and parathyroid glands. The author has collected into the relatively concise limits of a book of 261 pages the main facts at present known regarding the subjects of which he treats. The physiology, chemistry and pathological anatomy of the glands are considered in considerable detail, together with a description and discussion of the various forms of disease now supposed to be more or less directly associated with disease of the glands. A bibliography and an index complete the volume. The illustrations are somewhat crude, but adequate to show the conditions under consideration.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, FEBRUARY 1, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

*SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

MEDICAL REPRESENTATION IN THE
CENTRAL GOVERNMENT.

THERE is a growing feeling that medical men should take a more active part in political affairs and in the general concerns of government. The idea formerly held that a physician transcended his proper sphere when he extended his interests beyond the actual practice of his profession has, in great measure, given place to a more liberal point of view. It has again and again been demonstrated that the peculiar knowledge which a physician brings may often be of the greatest service in the framing of laws or in the conduct of various enterprises. The physician, therefore, is coming to occupy a less and less isolated position, and is making himself felt in matters not immediately concerning his technical professional work. Unfortunately, as our government is constituted, it is not possible for men eminent in medicine to devote the requisite time to the work of important legislative positions without giving up in great measure their professional work. It would, no doubt, be well if the medical profession were represented by certain of its most distinguished members in the United States Senate and the House of Representatives, but this, unfortunately, is not feasible, and the medical profession must content itself in this country with minor positions which carry possibly certain influence but very little authority.

It is of interest to turn from this situation to the conditions as they exist in England. There has for many years been a representation of medical men in the House of Commons, and often men of great eminence in their profession. In the recent parliamentary upheaval a considerable

interest is being aroused as to the character of the medical representation of the next parliament. A recent number of the *British Medical Journal* comments at considerable length upon the situation. The number of physicians in the last House of Commons was very limited, and the medical profession in England feels that the next should see a larger representation. There were but nine medical men in the house recently dissolved, and unfortunately some of these showed little interest in the medical questions coming before Parliament. Others, however, have taken a most active part in the discussion of matters bearing upon medicine, among which are such well-known names as the Rt. Hon. Sir Walter Foster, Sir John Batty Tuke, Sir Michael Foster, Dr. Hutchinson and Dr. Ambrose. These men are all seeking re-election. Sir Michael Foster's career in Parliament has been a peculiarly interesting one. He has represented the University of London since 1900, has gained for himself a place of influence, and has commanded the respect of both parties in his judgment concerning matters affecting the public health. He has strongly supported efforts for the improvement of vaccination, has interested himself in the tenure of office of medical officers of health, and in academic affairs has admirably represented the modern spirit which has done much to revivify the University of London. Sir John Batty Tuke has represented the Universities of Edinburgh and St. Andrew's and has been an active supporter of the British Medical Association. His interest in the various bills presented for the betterment of medical conditions has been unceasing and his activities have covered a wide range of subjects. The services rendered by Sir Walter Foster are hardly less deserving of mention, particularly in relation to the political situation of the medical profession. The other medical members, whose names we have mentioned, have also rendered valiant service in upholding the best interests of the medical profession.

Our contemporary, nevertheless, dwells upon the feeling of dissatisfaction with the work done in the House of Commons by its medical members. It also, very rightly, suggests the enormous difficulties which face the relatively few men in legislative office in securing the passage of the measures in which they and the profession at large are interested. The general situation in England, however, appears to be in some measure better than with us, inasmuch as men of the highest standing in their profession are placed in

positions of relative authority in which they may at least express and demand a hearing for measures of benefit to the profession and so indirectly to the people at large. Possibly in this country public opinion in a measure takes the place of this more direct representation, but we are disposed to think that much here might also be accomplished could we have a few fitting spokesmen for the profession of medicine at Washington representing various portions of the United States.

STUDIES IN AMEBIC DYSENTERY.

We have repeatedly called attention to the excellent scientific work being done at the Government Laboratories in Manila. Among the recent publications is a discussion of intestinal hemorrhage as a fatal complication in amebic dysentery and its association with liver abscess, a paper upon the action of the various chemical substances upon cultures of amebae and an investigation on the pathology of intestinal amebiasis. In all of these papers a definite contribution is made to our knowledge of diseases which occur too infrequently in this climate to render their investigation possible. Dr. Richard P. Strong in the first of these papers calls attention to the relation of hemorrhage in amebic dysentery to abscess of the liver. A study of this matter has led him to the conclusion that fatal intestinal hemorrhage in the disease under consideration probably will be shown to occur frequently in conjunction with hepatic abscess, although such an association is not inevitable. The investigation also shows that the diagnosis of liver abscess may be suggested by the occurrence of multiple intestinal hemorrhages in the course of amebic dysentery.

Dr. J. B. Thomas offers a useful discussion on the action of certain chemical substances upon cultures of amebae, and as a result of his experimentation reaches the conclusion that the most marked effect upon the growth of cultures is produced, among various other substances, by permanganate of potash in solution 1-2000, sulphate of quinine 1-500, nitrate of silver 1-2000, argyrol 1-500 and protargol in the same dilution. Each of these substances produces a marked effect on the growth within twenty minutes, due in most cases to the destruction or inhibition of the growth of the symbiotic cholera spirillum. From a practical standpoint this shows that there is no specific treatment for amebic dysentery, but it also indicates that there are various other drugs equal or superior to the much used quinine. As suggested by the writer of the paper, this will

be appreciated by physicians practising in the tropics among patients who for any reason cannot take quinine.

Writing on the pathology of intestinal amebiasis Drs. P. G. Woolley and W. E. Musgrave arrive at interesting conclusions regarding the ulcerative condition of the intestine caused by *Ameba coli*. This intestinal amebiasis is usually confined to the large intestine, but both the ileum and the appendix may be involved. Usually the cecum and the ascending colon are affected, but in the majority of cases the entire bowel takes part in the process. The ulcers show a tendency to be undermined and the organisms may enter the blood stream very early in the disease. The affection is a subacute inflammatory process and complete healing may be accomplished, or a condition of atrophic enteritis may persist which is known as sprue.

These admirable papers are profusely illustrated by finely reproduced halftone photographs, many of them of very high power. Such work is another evidence of the progress being made in the Philippines, not only toward general civilization, but also toward accurate scientific medical work, which must ultimately be far-reaching in its consequences, not only to the islands themselves but to the world at large.

MEDICAL NOTES.

EXTERMINATION OF MOSQUITOES. It is stated that a bill has been introduced into the New Jersey Legislature asking for an appropriation of \$70,000 a year for five years to be used in the extermination of mosquitoes.

THE DISTRIBUTION OF MOSQUITOES IN THE UNITED STATES. C. S. Ludlow reports in the *Medical Record*, Jan. 20, 1906, the results of the collections of mosquitoes made during parts of 1904 and 1905 for the purpose of determining what mosquitoes were present at the various army posts. The first collections were restricted to the southern states, but in 1905 all the stations of the United States were included in the work. The results are expressed in tabular form, and while it appears that *Anopheles maculipennis* and *Culex fatigans* are the two most widely distributed species, for details regarding the fifty odd other varieties mentioned, the original must be consulted.

COMMITTEE OF ARRANGEMENTS—AMERICAN MEDICAL ASSOCIATION ANNUAL MEETING, JUNE 1-8, 1906.—On Sept. 5, 1905, the president of the

American Medical Association appointed the chairman of the Committee of Arrangements, with the request that he nominate the members of the committee. The secretary and five members of the Committee of Arrangements were then appointed, each member being constituted the chairman of a committee, with the privilege of selecting his own committeemen, and his secretary, who should be the executive of the committee. The invitations to serve upon these committees were then issued by the secretary in the name of the Committee of Arrangements at the request of the chairmen of committees.

At a meeting of the Committee of Arrangements, held Dec. 8, 1905, it was voted that the secretaries of committees be made members of the Committee of Arrangements. Each committee may have as many sub-committees as it finds necessary, and each committee is final in its decisions, except when its action will affect (a) the general policy of the meeting, or (b) expense, — in which case the proposed action must be submitted to the Committee of Arrangements for approval.

The following is the announcement of the members of the Committee of Arrangements:

Chairman, Dr. Herbert L. Burrell, 22 Newbury Street, Boston, secretary, Dr. Robert B. Greenough, 8 The Fenway, Boston; Finance: Dr. George B. Shattuck, 183 Beacon Street, Boston, chairman, Dr. Frank B. Harrington, 201 Beacon Street, Boston, secretary; Section Meeting Places, General Exhibit, Printing and Programs: Dr. Reginald H. Fitz, 18 Arlington Street, Boston, chairman, Dr. Elliott P. Joslin, 81 Bay State Road, Boston, secretary; Hotels and Transportation: Dr. Charles Harrington, State House, Boston, chairman, Dr. David D. Scannell, 366 Commonwealth Avenue, Boston, secretary; Entertainments, Banquets, Ladies: Dr. J. Collins Warren, 58 Beacon Street, Boston, chairman, Dr. John C. Munro, 173 Beacon Street, Boston, secretary; Registration, Badges, Bureau of Information: Dr. Charles S. Minot, 688 Boylston Street, Boston, chairman, Dr. William T. Porter, 688 Boylston Street, Boston, secretary. The office of the Committee of Arrangements is at the Boston Medical Library, 8 The Fenway, Boston, Mass.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Jan. 31, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 38, scarlatina 30, typhoid fever 9, measles 180, tuberculosis 60, smallpox 0.

The death-rate of the reported deaths for the week ending Jan. 31, 1906, was 18.93.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Jan. 27, 1906, was 212, against 204 the corresponding week of last year, showing an increase of 8 deaths and making the death-rate for the week 18.58. Of this number 108 were males and 104 were females; 208 were white and 4 colored; 137 were born in the United States, 71 in foreign countries and 4 unknown; 44 were of American parentage, 141 of foreign parentage and 27 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 39 cases and 1 death; scarlatina, 37 cases and 4 deaths; typhoid fever, 10 cases and no deaths; measles, 185 cases and 3 deaths; tuberculosis, 48 cases and 21 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 41, whooping cough 0, heart disease 22, bronchitis 6 and marasmus 1. There were 7 deaths from violent causes. The number of children who died under one year was 44; the number under five years, 60. The number of persons who died over sixty years of age was 50. The deaths in public institutions were 75.

There were 6 cases and 5 deaths reported from cerebrospinal meningitis during the week.

DEATHS FROM CEREBROSPINAL MENINGITIS. — A number of deaths have occurred among the apprentices at the naval training station at Newport, R. I., from cerebrospinal meningitis. A few days ago eight deaths had been reported and there are still a certain number of cases under treatment. The disease has, apparently, also made its appearance in Cambridge, Mass., where within a week five cases have developed, three in one family. These cases were all in young children.

THE RELATION OF THE MEDICAL PROFESSION TO THE LAW AND THE COURTS. — Four lectures, on the relation of the medical profession to the law and the courts, will be delivered by Ezra R. Thayer, LL.B., in Lecture Room E, of the Harvard Medical School, on four successive Monday evenings, at eight o'clock, beginning Feb. 12. These lectures will be open to medical students and the profession. Such a course of lectures as this has long been needed. It is desirable that the close relationship which exists between medicine and certain departments of law should be emphasized, and especially that students and practitioners of medicine should have a clear idea

of the legal requirements of their profession. Mr. Thayer is admirably fitted to undertake the task of presenting the subject in an understandable way.

NEW YORK.

BERI-BERI.—In the first of the Cartwright lectures for 1906, delivered at the New York Academy of Medicine on Jan. 25, Baron Takaki devoted his attention largely to the subject of beri-beri. He stated that this disease, which was formerly a very prolific source of death, has now been exterminated in the Japanese navy, and that this result was effected by the substitution to a considerable extent of nitrogenous food for the disproportionately large percentage of carbohydrates formerly employed. On Jan. 28, Dr. Louis I. Seaman gave a reception for Baron Takaki, which was largely attended.

NEW SERUM IN TREATMENT OF EXOPHTHALMIC GOITRE.—At a meeting of the Medical Society of the County of New York, held Jan. 22, reports were made of the successful use of a new serum in the treatment of exophthalmic goitre. This serum, it would appear, can be made only from the diseased thyroid gland of the human subject. The first experiments leading to the discovery were made by Dr. S. T. Beebe of the Loomis Laboratory, Cornell University, who obtained the thyroid of a patient who had died of Graves's disease and injected material from it into rabbits, afterwards preparing the serum in the same way as other serums. The new serum was first employed practically in the treatment of cases of Graves's disease by Dr. John Rogers, instructor in clinical surgery in the Cornell Medical School, and afterwards by Dr. W. Gilman Thompson, Professor of Medicine, and in every instance, so far, it has been attended with positively curative results. It is stated that one of the patients treated by Dr. Thompson was almost at the point of death, and now has been completely restored to health. The course of treatment is a short one, a small quantity of the serum being hypodermatically injected every second day for a period of about two weeks, and the cure appears to be permanent.

POSSIBLE ENCOURAGEMENT OF QUACKERY

Quackery of various kinds will receive a certain amount of encouragement from and no doubt make the most of an elaborate dissenting opinion which Justice Deuel of the Court of Special Sessions has filed in the case of an exponent of "Neuro-Mechano-Therapy" against whom the County Medical Society had secured a conviction

and punishment by fine for practising medicine without a license. In commenting on this, the *New York Times* admirably says that this judge "was able to see validity in the contention, so lamentably familiar to everybody who has followed the desperately persistent attempts of the ignorant and unqualified to break into the medical profession without going to the trouble of studying medicine, that nothing is 'the practice of medicine' except the administration of drugs."

It is his opinion that a man may advertise himself as a doctor, may hold himself out to the public as competent to diagnose and treat every malady from which human kind suffers, and may take such fees as trusting patients choose to pay, but if he refrains from giving drugs he is not a practitioner of medicine and does not come under the law which insists that doctors must have a reasonable minimum of special education for their work.

We shall watch the literature of quackdom with interest to see how soon its purveyors forget to note the fact that Justice Deuel's opinion was a dissenting one. It will not be long."

Miscellany.

IMPURE DRUGS AND PROPRIETARY MEDICINES.

At the meeting of the New York Academy of Medicine on Jan. 18, impure drugs and deleterious proprietary medicines were the subjects of discussion. Dr. H. M. Biggs, medical officer of the Health Department, expressed the opinion that all drug stores should be placed under official supervision. It was scarcely realized, he said, how completely the physician was at the mercy of the pharmacist. In a very large number of the New York shops the drugs sold are either inert or adulterated with active poisons like wood alcohol. Even the large houses are not free from guilt in this matter. What, then, can be expected from the small dealers? Drs. Hirschman and Atkinson, of the department, then gave some of the results obtained from the examination of samples purchased in the drug stores, fully substantiating the statements of Dr. Biggs. Dr. George I. Peabody emphasized the harm done to the public by the secret preparations so widely advertised, and cited a number of instances in point. A certain predigested beet extract analyzed at Harvard contained 30% of alcohol, and if the dose directed were taken, the patient in the course of a day would take 14 oz. of nutriment and 6 oz. of whiskey. A certain preparation also contained 30% of alcohol, and in 64 sorts of tonics and bitters, the percentage of alcohol varied from 21 to 42. We cannot prevent a man from buying what he wants, he said, but we should insist that he should be informed

of the real character of what he does buy. To accomplish this, Dr. W. Gilman Thompson asked the support of the Academy for a proposed bill compelling the labelling of all proprietary medicines with a statement of their ingredients, with the quantity of each, and imposing a heavy fine for infractions of its provisions. Resolutions were then adopted urging the council of the Academy to take action in the matter, and also to bring to the attention of the Health Department the action of the Massachusetts Board of Health in preparing a list of harmful preparations.

A UNIQUE CASE.

Dr. P. F. O'HANLON narrates the following "Coroner's Case," in the *New York Medical Journal*: "A man, G. B., was taken to the House of Relief by its ambulance in a state of collapse following three days of gastric disturbance of which constant vomiting was the most predominant symptom. He died. The autopsy revealed a lump or tumor in the small intestine two feet from the ileocecal valve. It was movable. That part of the intestine from the point of tumor to the valve was collapsed, behind the intestinal tube was markedly dilated. Opening the intestine the tumor was seen, its form oval and as large as a goose egg. It had the appearance of fat. It was not decided at the autopsy what it consisted of. One half of the substance was sent to Dr. Roper, of the New York Hospital Laboratory, and the remaining to Dr. Hodenpyl, of the College of Physicians and Surgeons.

"After a time these gentlemen made the report that the tumor was a peach. The statement was made after making sections and microscopic examinations, and comparing with fruit of the above named kind.

"How or in what manner the deceased was able to do this trick which ended his career remains, after most diligent inquiry on my part, a mystery, but a most truthful and interesting fact."

THE STATE BOARD OF CHARITY ON DR. BOWDITCH'S DISMISSAL.

WE find the following statement on page 75 of the Twenty-seventh Annual Report of the State Board of Charity of Massachusetts which is just issued:

"In the opinion of the Board, the dismissal of Dr. Vincent V. Bowditch from his post of visiting physician, for the reasons given by the trustees to the Board, is an injudicious and regrettable step. From the very beginning Dr. Bowditch has been identified with the institution, has served it with skill and devotion, and has contributed greatly to its success and prominence. Owing to early difficulty in finding a competent medical superintendent, the trustees placed the medical direction of the Sanatorium in the hands of the two visiting physicians from Boston, Dr. Bowditch

and Dr. Clapp, their work being supplemented by two medical assistants at Rutland. This arrangement has been inconvenient and imperfect, becoming more so with the steadily increasing numbers at the hospital.

"The time would seem to have come for a change in the method of management, and for the appointment of a resident specialist in tuberculosis; and the Board strongly urges such a change."

Correspondence.

IMMUNITY AGAINST TUBERCULOSIS.

DORCHESTER, MASS., Jan. 25, 1906.

Mr. Editor: Apropos of the campaign of education on the subject of tuberculosis, a recent valuable book entitled "The Principles of Heredity," by G. Archdall Reid, discusses an aside of the question ordinarily overlooked, in such an attractive way that perhaps it will interest your readers to hear a few extracts. The author first discusses tuberculosis as an evolutionary force, showing that the present day course of evolution is mainly directed against disease, to produce immunity by natural selection. He shows that racial immunity against tuberculosis has been partially secured in the Anglo Saxon; but points out that individual immunity is never secured as the result of an attack. Hence it follows that by fostering those who are susceptible, we perpetuate the disease, by deferring the production of a completely immune race. Though these ideas are by no means new, their exposition is most striking.

"It is universally admitted that men differ greatly in their susceptibility to infection and in their powers of subsequent resistance. If, then, a lethal disease be very prevalent it is evident that it presents a very stringent form of natural selection. In England, for example, hardly anyone escapes measles, whooping-cough, or tuberculosis unless he be immune, or death, unless he be resistant. Selection should cause an evolution of an inborn power of resisting infection, or of an inborn power of recovering from infection. The two qualities are quite distinct, and are generally useful against quite distinct diseases. Tuberculosis should cause an evolution of what we know as inborn immunity, while measles should cause an evolution of something quite distinct, the inborn power of acquiring immunity.

"We habitually speak of the fatal 'climate' of the west coast of Africa, but we are usually unaware that our own 'climate' is nearly as fatal to the native inhabitants of the greater part of the world. The micro-organisms of tuberculosis are unable to persist except under given conditions, which are best satisfied in the crowded, badly-ventilated houses of civilized people, particularly those who dwell in the cities of cold and temperate climates. That the environment is yearly growing more favorable to the bacilli in the world at large cannot be doubted, and this in spite of the greater attention to light and ventilation. Our race, which is able to persist under such adverse conditions, has undergone evolution in regard to tuberculosis, fully equal to the evolution against malaria undergone by the West Africans. It is clear that the individuals of our race are very generally so resistant to tuberculosis that, even after infection, their phagocytes, under slightly improved conditions, are able to wage successful war against the microbes. It is clear, also, that no immunity can be acquired against the disease because those who have recovered may, under worse conditions, take it again. But in the very lands in which the least resistant among us recover from previous infection, tuberculosis is causing extermination of the natives. This one fact throws the greatness of our evolution into startling relief, for the natives usually live under hygienic conditions that are far better as regards the disease than do the settlers. No race is now able to achieve civilization, to dwell in dense communities, unless it has previously undergone evolution against tuberculosis. It is a

highly significant fact that throughout the New World no city has its native quarter, whereas every European settlement in Asia and Africa has its native suburb. The aborigines of the New World are now found only in remote or more or less inaccessible parts. The following is an example of the manner in which tuberculosis went to work; the tribe of Hapua is said to have numbered some four hundred, when the smallpox came and reduced them by one fourth. Six months later a woman developed tubercular consumption, the disease spread like fire along the valley, and in less than a year a man and a woman died from the newly created solitude.

"We see clearly how little the conscious efforts of man have influenced his destiny. We see forces, unrecognized, enormous, irresistible, unchanging, working slowly towards tremendous conclusions, forces so irresistible and unchanging that, watching them, we are able even to forecast something of the future."

The writer's view on the possibility of completely eliminating tuberculosis are significant.

"But in all probability this reduction of mortality from consumption, though it may continue till all slums have quite disappeared, is not permanent. As generations pass, as the race regresses, as the numbers of the night increase through lessened elimination, the task of the sanitary reformer will grow in magnitude and complexity. The disease is difficult to detect in its earlier stages, especially in very resistant sufferers in whom it may exist unsuspected for months or years. Every such person is a focus of infection. We can hardly expect in our climate, and with our social habits and dense population, to render the conditions as unfavorable to the bacilli as they are in tropical Pacific islands, where the natives are becoming extinct. Segregation of consumptives to any degree of completeness is impracticable, not only because of their enormous numbers, and of the difficulty of detecting the disease in its incipient stages, but also because of their long duration of quarantine necessary. Apparently, therefore, our only hope of permanently lessening the prevalence of the disease lies in a reduction of the number of people susceptible to it. In other words, the problem presented by consumption will have to be solved, if ever it be solved, by the student of heredity. Some method will have to be devised to lower the output of children by people predisposed to the complaint, otherwise the mortality from consumption cannot be greatly or permanently reduced. A few states of the American Union have already laws forbidding the marriage of consumptives. It is, however, no part of my present purpose to suggest remedies, for the mere discussion of which the community is not as yet prepared. My principal object is to demonstrate that there are certain practical problems of great importance which cannot be dealt with until the public, and, especially the medical profession, are in a position to bring an adequate knowledge of heredity to bear on them."

Trusting that these extracts will introduce others to this most interesting book.

Sincerely yours,

LAWRENCE W. STONG, M.D.

ROSENBERG'S THEORY OF THE DEVELOPMENT OF THE SPINE.

A CORRECTION.

HARVARD MEDICAL SCHOOL.

Jan. 24, 1906.

Mr. Editor: The following passage occurs in Dr. Bohm's very interesting article which appeared in the *Journal* of Jan. 25: "In the development of the species man out from lower species 'the dum' travels upward on the spine' (Twilight), a loss of vertebrae takes place gradually. From this standpoint human individuals which have six or five and one-half human vertebrae would represent a lower type of human beings. According to this theory our patients would belong to this class and their deformities are of atavistic character."

Dr. Bohm entirely misstates me. I know that I have done unintentionally but in view of my position, which is supported by recent discoveries, I wish to correct the error. In two words the case is this: Rosenberg many

years ago declared that in the early human embryo the dum joins the sacrum further back than in the adult and that during development it moves forward upwards along the spine. If it stops at the twenty-sixth vertebra it is an effect of atavism. If it goes on to the twenty-fourth it is (presumably) a step to the future. This doctrine had a great vogue because it seemed so pretty an illustration of the alleged law that ontogeny repeats phylogeny. Hott and some others denied the facts most accepted then. For my part, not being a practical embryologist, I allowed the theory to pass as a working hypothesis. I showed, however, that even if true this migration of the dum was inadequate to account for certain important changes. Recently, however, Harkness (*Anatomischer Anzeiger*, 194, 1901) has shown that the earliest trace of an illum is opposite the upper part of the lumbar region and that it travels downward. Thus he not only demolishes Rosenberg's theory but all the sham science that has come from it. The quotation which Dr. Bohm gives from my paper on spines is from a part in which I am merely stating Rosenberg's views.

Very truly yours,

THOMAS DWIGHT, M.D.

ERRORS IN THE HARVARD MEDICAL SCHOOL HISTORY.

LOWELL, MASS., Jan. 26, 1906.

Mr. Editor: In your issue of Jan. 25, 1906, Dr. Edward M. Buckingham, in a communication, refers to what he terms "Errors in the Harvard Medical School History," relative to the biography of his father, the late Dr. Charles E. Buckingham. Permit me, through your columns, to state that, difficult as it is for biographers to harmonize varying estimates of individuals, such varying estimates do not constitute errors. If your correspondent had quoted the whole paragraph rather than detached portions, I think impartial judges would conclude that there was nothing stated therein to deserve the implication of error. That the late Dr. Buckingham was a fearless critic and that his criticism was often bitter does not imply that such criticism was animated by "a mean jealousy of others," nor that it was aroused by the "better fortune in others." Here is the whole paragraph from which your correspondent quoted, the italicized words he does not use.

Vol. II, p. 867. "In his early professional career Buckingham was often in sore straits. His means were small and he was without family influence and social connections. These difficulties did not discourage him; on the contrary he was stimulated by necessity to make his own way. The struggle, however, left its scars, and once he had afterwards a better and sometimes a luxurious life, he was often possessed these advantages which he had lacked. As our hero's case was more just than he was, and as those whom he thought had treated him unjustly, he was more ready to debate than he. He often felt that he was an able journalist, that vigorous style, open to criticism, and a forthrightness of expression. He was a man who often exhibited in various forms of criticism, and unmarked double dealing."

In reference to the father and mother's careers, it is an undisputed fact that the death of the Harvard School was due directly to the fact that its leaders to the Harvard School of Harvard Summer School. Many of these men held clinical positions similar to Dr. Buckingham in the House of Industry and such men were selected by the Harvard Medical faculty, for the instruction which the expanding Harvard School required. These appointments were not always satisfactory. The corporation and do not appear at all surprising. Much confusion has resulted from the fact that the date at which a teacher was selected for the Medical Faculty with that at which he was elected to the Harvard School. The distinction is important, as it was not until teachers who served prior to 1870.

Very truly yours,

THOMAS DWIGHT, M.D.

Author, *History of the Harvard Medical School*.

RECORD OF MORTALITY

* Note as last reported.

Deaths reported, 3,073; under five years of age, 886; principal infectious diseases (smallpox, measles, cerebrospinal meningitis, diphtheria and croup, diarrheal diseases, whooping cough, erysipelas, fevers and consumption), 589; acute lung diseases 568, consumption 323, scarlet fever 17, whooping cough 14, cerebrospinal meningitis 25, smallpox 0, erysipelas 11, puerperal fever 10, measles 25, typhoid fever 17, diarrheal diseases 73, diphtheria and croup 67.

From whooping cough, New York 5, Chicago 1, Baltimore 6, Boston 2. From scarlet fever New York 10, Chicago 6, Boston 1. From cerebrospinal meningitis, New York 15, Boston 4, Worcester 1, Cambridge 1, Lowell 2, Somerville 1, Weymouth 1. From erysipelas, New York 6, Chicago 3. From typhoid fever, New York 5, Chicago 4, Baltimore 1, Boston 5, Worcester 1, Cambridge 1. From measles, New York 17, Chicago 3, Providence 1, Boston 4, Westfield 1. From diphtheria and croup, New York 46, Chicago 9, Baltimore 2, Providence 1, Boston 3, Lawrence 2, Lynn, Haverhill, North Adams and Waltham 1 each.

In the seventy-six great towns of England and Wales, with an estimated population of 15,818,300, for the week ending Jan. 13, 1906, the death-rate was 16.7. Deaths reported 5,652;

acute diseases of respiratory organs (London) 193, whooping-cough 101, diphtheria 66, measles 124, smallpox 0, scarlet fever 42.

The death-rate ranged from 6.1 in Northampton to 25.9 in Burnley; London 17.5, West Ham 14.2, Brighton 19.5, Southampton 15.1, Plymouth 15.0, Bristol 19.1, Birmingham 16.6, Leicester 17.7, Nottingham 18.2, Birkenhead 14.7, Liverpool 21.2, Wigan 17.3, Bolton 13.9, Manchester 17.5, Salford 14.5, Halifax 18.1, Bradford 15.7, Leeds 18.6, Hull 14.3, Sheffield 13.3, Newcastle-on-Tyne 16.5, Cardiff 13.6, Rhondda 13.5, Merthyr Tydfil 24.3, Walthamston 10.3.

METEOROLOGICAL RECORD.

For the week ending Jan. 20, in Boston, according to observations furnished by Sergeant J. W. Smith of the United States Signal Corps:

SOCIETY NOTICES.

THE BOSTON CITY HOSPITAL ALUMNI ASSOCIATION.—The Association will hold its annual meeting at Hotel Tueries, 270 Commonwealth Avenue, between Fairfield and Gloucester streets, on Wednesday evening, Feb. 7, at 6.30 o'clock. Dinner will be served at 7 o'clock immediately after the business meeting. Dr. Charles H. Williams will preside.

WILLIAM H. ROBEY, JR., M.D., *Secretary.*

HARVEY SOCIETY LECTURE.—The seventh lecture in the Harvey Society course will be delivered by Prof. Frederick S. Lee, of Columbia University, at the New York Academy of Medicine, on Saturday, Feb. 3, at 8.30 p.m. Subject, "Fatigue."

GEORGE B. WALLACE, *Secretary.*

APPOINTMENT.

DR. DAVID CHEEVER has been appointed third assistant visiting surgeon at the Boston City Hospital.

RECENT DEATHS.

DR. WILLIAM B. NEFFEL, of New York, died on Jan. 20. He was born in Russia in 1830 and was graduated from the University of St. Petersburg in 1852. During the Crimean campaign he served as surgeon to the Russian Imperial Guards. In 1865 he removed to New York, where he devoted himself more particularly to neurology and was one of the pioneers in electro-therapeutics. Dr. Neffel's wife, who survives him, was the Princess Nadine of Georgia, a granddaughter of the late King George XIII.

DR. THEOPHILUS CARTER, of Mount Vernon, Westchester County, N. Y., a specialist in nervous diseases, died on Jan. 23, at the age of forty years. He was a graduate of the Yale medical school and settled in Mount Vernon twelve years ago. About three years ago he was obliged to retire from practice on account of ill health.

Address.

THE PROBLEM OF PSYCHIATRY IN THE FUNCTIONAL PSYCHOSES.

BY EDWARD COWLES, M.D., BOSTON.

(Continued from No. 5, p. 121.)

THE RELATION OF PATHOLOGY TO OTHER BIOLOGICAL SCIENCES, ESPECIALLY TO PHYSIOLOGY.

PHYSIOLOGY, when it declared itself an independent science by breaking away from medicine and establishing its place in the great realm of biology, entered upon a broader field of study of the functional side of life with its complex phenomena in the functions of all living matter. To morphology, as an equally independent science, belongs the study of the structure and form of living matter; it covers the whole field of anatomy in the special forms of zoology and botany. But physiology and morphology, which are closely woven together, are both built upon the foundation of the inorganic elements of inanimate matter with its controlling laws of physics and chemistry that govern the forces of inanimate phenomena. All these forces of animate and inanimate nature are bound together; from a biological point of view we do not know living matter without both form and function.

On the part of the physician the inquiry at this point is as to the true relations of pathology to the other biological sciences in medicine. The scientific foundation of pathology, the development of its work in the other sciences which it necessarily involves, support its claim to an equal place in biology with the other natural sciences.

Professor Orth, in an address at Kassel in 1903, described pathology as consisting of two branches, anatomy and physiology. Although the great Virchow remained a pure pathological anatomist, he contemplated the beginning of pathological physiology as the culmination of his endeavors. "one of his favorite themes was the establishment of pathological physiology, a subject which, to his mind, was the foundation of scientific medicine, and therefore of medicine as a whole." Practical medicine, according to Virchow, is co-extensive with pathological physiology; this is founded on pathological anatomy, clinical observations, experimental researches; its problem is the determination and investigation of bodily processes under abnormal conditions, of illness and its symptoms. Virchow's experimental investigations to clear up morphological characteristics of disease go only to the beginning, and Professor Orth urged that better attention should be given to physiological methods for the determination and interpretation of functional disorders in the unhealthy organ, yet pathological morphology must remain the unchangeable groundwork of all medical knowledge and thought, its most important function is its purpose for the upbuilding of pathological physiology, for the understanding of the living processes and their disturbances in the sick body.

Bacteriology in its marvellous progress leads

investigation directly into the field of pathological physiology, and finds explanations in the normal physical and chemical reactions that belong to the normal cell physiology. Pathology, taking bacteriology into its special province, is engaged in the study of problems relating to the nature of disease. General physiology has shown that the physico-chemical reactions in living substances are fundamental and essential factors in the production of vital phenomena; it finds, in its investigation of the component elements of cell-substance, that in physiological chemistry is its chief aid in the explanation of vital activity and its disorders. Hertel⁹ reviews our present knowledge of the chemical defences of the organism against disease; it serves to emphasize the varied chemical activities of the cells, and to render more intelligible the phenomena of diseases that result from modifications of failure of these cellular functions. He says: "Modern pathology has made us familiar with the conception that disease is generally the expression of a reaction on the part of the cell to injurious influences. The only rational conception of the ability of the human body to defend itself against disease by means of chemical agencies is that these defences ultimately reside in the cells themselves. Many of the phenomena of disease are caused by the modification of function that occurs during the action of the cell in resisting injurious influences." Ernst¹⁰ has shown that, notwithstanding the great obscurity of the subject and the somewhat conflicting theories, the point is maintained that in all reactions the cell activity intervenes at some stage of the production of immunity, and that most probably the reactions that occur are closely related to these that go on under the ordinary conditions of tissue metabolism. These considerations are consistent with the fundamental doctrine of cell physiology and pathology.

It appears from a brief survey of the history of pathology that when at first it was a part of anatomy, it was then pre-eminently morphological, and that this characteristic motive still prevails to a large degree. After it became independent, pathology concerned itself especially with deviations from the normal anatomical standard. It developed new relations with the other biological sciences as they attained existence, and like morphological problems arose in connection with them. There was mutual receiving and giving of aid, but anatomy was the parent science and the study of the concrete facts of structure being easier than ever-changing function, morphological conceptions have always kept in advance and pathology has held them to be essential in giving finality to its explanations and proofs. But with the slowing of progress in normal and pathological histology has approached the frontiers of present attainable knowledge in the speculative theories of structure in the endeavor to prove, apparently, an essential natural realities of structure by reference to the facts of physiological activity. The latter and

⁹ Hertel, C. A. "Chemical Pathology," 1905.¹⁰ Ernst, H. C. "Modern Theories of Bacterial Immunity," 1903.

pathology reveals evidence in support of the conclusion that, from the beginning, the science of pathology has needed first the data of normal form and function in order to study their deviations; also pathology has been steadily tending to the finding of its ultimate dependence upon physiology. Aside from the results called disease from actual traumatism of cell bodies caused by extrinsic agencies, there must be many transient conditions of intracellular rearrangements or molecular disorder, beginning with functional and defensive reactions, long before there can be any ascertainable structural findings. Such molecular changes, beyond the ken of the microscopist, might be assumed to be structural in fact; but the ultimate problem of the search for explaining principles thus tends to become a physico-chemical one. The facts of cell functions should hold an important place in the study of the varying agencies and influences of cell stimulation in the production of symptoms. The relation to physiology of the morphological side of pathology is especially instructive.

THE RELATION OF MORPHOLOGY, NORMAL AND PATHOLOGICAL, TO PHYSIOLOGY.

Morphology presents considerations of the highest importance, which require special notice in this examination of the mutual relations of the biological sciences. It is granted that pathology, on the morphological side, is inconceivable without normal anatomy as its basis. Pathological anatomy, being dependent on normal anatomy, belongs to the science of morphology. This science, with its great subdivision of embryology, has attained splendid achievements; in the course of its advancement in many specialized lines of investigation in plant and animal life, it has enjoyed the advantage of being able to study the problems of evolution and development in many quickly succeeding generations of vital forms. The scope of its observations has extended farther than from the point of view of medicine, and is reaching conclusions that may yet illuminate some of the dark places of psychiatry. The history of morphology has a special significance in its development cotemporary with other biological sciences; the changes in its course suggest a law of progress in scientific research that has operated in other fields. After the emergence of morphology and of physiology from the keeping of anatomy, the two new sciences entered upon equal domains in the realm of biology. Morphology asserted the independence of the science of form and structure from that of function; the doctrine was that form persists and function varies. It was characterized by the conception of a fixity of types, a rigid adherence to the study of mature forms which it labored to arrange in a perfected and systematic classification. With the breaking away from these rigid conceptions, during the last fifty years, the course of progress was in the study of the problems of evolution; leading through the investigations concerning the origin of species, it

has come to the recognition of the supreme importance of the problems involved in the development of the individual and of the biological laws that govern it and the wide range of variations that may be produced in members of a given species. So in medicine, instead of clinical types, the differentiations of disease are becoming genetic and developmental in character.

In the morphology of plant and animal life it is agreed on both sides that they are subject to the same laws; in both plants and animals there are identical processes which are consistent with the significance of the cell-doctrine as being fundamental to morphology. In the close relation of form and function the modern conception is that the structural characters of which an individual organism is made up correspond to its functional characters; form characteristics cannot be understood without considering the function characteristics. Physiological characteristics are transmissible in the same way as the morphological. The study of physiological cytology and embryology is revealing the mechanism of the transmission of qualities; with the aid of the experimental methods in the production of variations in both form and function there is great progress in the understanding of the laws of descent and inheritance. The close relation of physiological and morphological characteristics proves that the problems of form and structure are also physiological problems. Physiological processes are influenced and often controlled by the conditions of the environment, both internal and external, and it is held that mental as well as physiological characteristics are inherited under the same laws. These brief references to the data of morphology serve here to indicate the trend of progress in this science; it points to the conclusion that influences which stimulate functional activity play an essential part in determining the processes of development and the resulting structural forms. The demonstrations of the dominance of the sensory over the motor side of the nervous mechanism is consistent with the fact that all movements are primarily a response to sensory impressions and are performed under their guidance. It follows from the teachings of Hughlings Jackson that cell-groups are thus formed by a process of education. All motor phenomena being responsive reactions to stimuli applied to the neuro-muscular mechanisms, the laws of use and habit influence functional activity and growth. The unity of all these sciences is also shown. Physiology and morphology have to do with interdependent manifestations of organic existence; there can be no disease until there is first normal life with whose physical sequelae pathology has to deal. Inasmuch as the whole science of pathology must refer all its material to normal standards, both on the functional and the morphological side, a like freedom belongs to the minor province of mental pathology; psychiatry is at least justified in seeking directly its immediate explanations in the hopeful, though neglected, field of function.

THE PATHOLOGICAL CONCEPTIONS OF PSYCHIATRY STATED IN TERMS IMPLYING MORPHOLOGICAL IDEAS.

In such a survey as this, of so complex a subject, certain difficulties have appeared concerning special aspects of current effort in the field of the psychiatrist's labors. Allusion has been made to the remarkable fact of the disharmony between mental physiology and mental pathology. There are signs of the coming of better co-operation, but so far the general fact is that the psychiatrist borrows from psychology what seems fitting with his pathological conceptions, and applies some of its psycho-physical methods; at the same time he hesitates to use the data and even the terminology offered by expert investigators in mental physiology. The importance of care in the use of descriptive words has been mentioned; an inquiry like this draws special attention to this subject and some extraordinary facts are revealed that should receive further notice.

First among these may be mentioned the use of the word "physiological"; its frequent infelicitous employment by both pathologists and psychologists themselves emphasizes the width and depth of the traditional gulf between mind and body. The distinction is commonly made between *psychical* phenomena and *physiological* phenomena, and the designations "mental side" and "physiological side" are used to make the same contrast. Mental phenomena are themselves physiological, but the usage implies a distinct psychical element as an extra-physiological epiphenomenon, when such a meaning is not intended and is therefore misleading. The mind event and the brain event are both physiological.

More remarkable examples of doubtful usage, universal in medical literature, and with far-reaching effects, are shown in the words "disease-form," "disease-entity," "disease-process" and "pathological process," which have already been mentioned. These words still suggest old meanings now wholly obsolete; this is so obvious that when thoughtful writers use such words for "convenience," the explanation is not infrequently made that it is not intended to imply that disease is a malign entity which invades the living body and works its evil course. Yet, as usage sanctions it, writers continue to employ the framework of words which would once have expressed the ancient parasitic personification of disease. While, in the science of pathology, this extreme conception is corrected by explanation, such words in their modern usage still embody and positively convey the sense of an underlying morphological counterpart of the symptom-complex that runs its course of progressive degeneration as a disease and reveals the terminal changes in post-mortem findings. To speak of all disease in terms used in these senses is to emphasize structural conceptions of pathology, and thus to impede the progress of the reform which is clearly seeking to give adequate attention to functional conceptions in place of the dominating demand for mature types and forms and classifications.

It would be interesting to follow out the history of the usage of these verbal embodiments of whole theories. Perhaps a reference to main points will be enough to indicate the purport of these statements. First, as to the nature of disease, it cannot be correctly conceived as a state of disordered activity or disorder of a process in an *active* sense; there is a condition produced by a defensive contest between the forces of the living cell and the harmful agencies; it is not a state of perturbed activity, but the result of it in diseased organs or tissues. The causes of disease are extraneous and unnecessary to cell life, which can exist without disease. The only true *process* in living organisms is the physiological or life process; the forces that cause the reactions called vital phenomena are inherent and are governed by the uniform laws of an invariable order of nature; like effects result from like causes and conditions, and the life process presents the attributes of uniformity and continuity controlled by the laws of descent. Reproduction is an original property of living matter and life is continuous, and death is not due to such a property; this is a proposition in which there would be a general agreement with Weissmann. Roger¹¹ reduces the conception of death to the formula: "Death is the result of an arrest of cellular nutrition; whatever the multiple proceedings are that are called into play, the final result is always the same."

A "disease-process" or "pathological process" cannot be conceived as comparable with the physiological process; the causes of disease being extraneous to normal cell life, are accidental, multiple, discontinuous, without uniformity. It is consistent with this, that even in the problem of tumor growths there are some essential explaining facts; whatever of the various theories may be employed to account for them, they are not indwelling entities, but depend for their existence upon the inherent vitality of the parent organism, acting under abnormal conditions. When the organism dies, new growth dies, there can be no disease without prior normal life.

When applied to functional disorders, the assumption of a necessary correlation between a "disease-form" and an underlying structural "disease-process" goes beyond the province of morphological pathology; it involves the intracellular changes of physiological chemistry. It is obstructive of a true conception of the wide variations of function that belongs to molecular nutritive and metabolic changes due to variations in condition, irritability, intensity of stimuli, etc., though affecting the same physico-chemical operations by the same agencies. But an authoritative insistence upon the "disease-form" and "disease-process" ideas, with respect to all psychoses, has undoubtedly tended to distract attention from a free consideration of the natural conceptions of mental pathology. These and kindred forms of words, with their distinctly morphological stamp, show the characteristic of

¹¹ Roger, G. H. Introduction to the Study of Medicine. Trans. 1901.

degree, of changing conceptions of pathology. They are kept in use by their convenience; and they appear to be in harmony with certain accepted theories and doctrines concerning the nature of disease and death and their relation to life. The influence of these doctrines is so great as to require examination here.

The difficulty of determining a sharp limit between life and death has been stated by Verworn¹²; there is no definite time at which life ceases and death begins in a complex organism, for one set of cell complexes may survive another for a long time; but "there is a gradual passage from normal life to complete death which frequently begins to be noticeable during the course of a disease. Death is developed out of life." "Thus death does not come to the cell immediately, but is the end-result of a long series of processes which begin with an irreparable injury to the normal body, and lead by degrees to a complete cessation of all vital phenomena." It is reasoned that "life and death are only the two end-results of a long series of changes which run their course successively in the organism"; also that "death undergoes a development; normal life upon the one hand and death upon the other are merely the remote end-stages in this development, and are united to one another by an uninterrupted series of intermediate degrees." This transition from life to death is termed *necrobiosis*, a word introduced into pathology by Virchow and Schultz; it is understood to mean, according to Verworn, "those processes that, beginning with an incurable lesion of the normal life, lead slowly or rapidly to unavoidable death."

Thus the principle of necrobiosis is to be studied in the cell as well as its vital phenomena; and it is held to apply also to the death of compound organisms. By an extension of this conception it explains the condition of natural death in old age, which thus appears to be physiological. Senile atrophy, which leads finally to death from the feebleness of old age, is to be regarded as simply the end-result of a long developmental series; death in old age is the natural end of an unbroken development and its causes exist in the living organism itself. Life itself never becomes extinct, but there is a continuity in its descent; yet living substance itself, in the form of bodies, is continually dying.

Compare with the foregoing the views presented by Gowers¹³ in regard to "diseases from defect of life" to which he gives the designation "abiotrophy" to distinguish a newly differentiated clinical group of conditions and symptoms; he acknowledges Mott's cotemporary recognition of these conditions. The conception is that of "a degeneration or decay in consequence of a defect of vital endurance"; it indicates a failure of life-processes due to defective vitality which seems to be inherent. It is recognized that many degenerative diseases of the nervous system are a result of such defect. The idea is expressed by

Mott¹⁴: "The neurones of a particular system die prematurely, owing to an inherited or acquired want of durability, and the regressive process of decay may be looked upon as a nutritional failure on the part of the same cells to maintain that metabolic equilibrium essential and correlative to functional activity." Every nerve cell of the human body is conceived to be "endowed with a specific durability whereby in the health-perfect organism every neurone possesses an equally adjusted vital energy." This is a statement of one of the two ways in which the regressive process occurs, the other being "the metamorphosis incidental to old age manifested by a gradual and general enfeeblement of the functions of the whole nervous system." "In contradistinction to this normal senile decay are the premature pathological processes of decay attacking groups, systems, or communities of neurones subserving special functions." "The process may be regarded as the inverse of development"; in harmony with these views Hughlings Jackson is quoted in regard to the helpfulness of considering diseases of the nervous system "as reversals of evolution, that is, as dissolution." Mott conceives that the process of primary degeneration is, morphologically, an evolutionary reversal commencing in the structures latest developed.

In the extensive literature concerning the life-processes and their failure in disease and senility, other diverging views may be cited, but the purpose here is only to indicate certain ideas and reasonings that bear upon the pathological conceptions with which psychiatry has had to labor. With respect to physiological old age ending in natural death the contending view is that the decline of life manifests the summation of the effects of external injuries, the damage of wear and waste, and is not something different and apart from disease. It is to be noted in the doctrine of necrobiosis that the idea of a "disease-entirety," with its course and process parallel and antagonistic to the life process, is avoided by conceiving life or the life-principle as the sole producer of two series of developmental processes, one of which leads to its end-result in the existence of normal being; this life-process is then conceived as turning against itself in another process of producing a series of decrements that reaches to the end-result of non-existence. One result must exclude the other, and we admit that death is the common goal; the life of every living thing ends in death and there is only one end-result, — death is developed out of life. But by shifting the position to the larger view, the attempt is to set up a dual conception of two processes, equal, parallel, antagonistic, yet conjoined. The truth is that the whole of life comprehends all living nature; the individual parts that bloom, fructify, and perish, and the fragments chipped and sloughed off from the great embodiment of life in matter, are always dying or dead, but the one chief process of life goes on, and we say that life is developed out of death.

¹² Verworn, M.: General Physiology. Trans., 1899.

¹³ Gowers, W. R.: Abiotrophy. Lancet, 1902.

¹⁴ Mott, F. W.: The Degeneration of the Neurones. Croonian Lectures, 1900.

The minor casualties of injury and disease represent the chance encounters of living substance, in its struggle for existence, with the discontinuous opposing forces of the world of living and material things. Living substance dies, but life is immortal. We may describe, in such figures of speech, the dual developmental processes with their contrasting end-results.

The paradox of the "processes" appears also in the application of the doctrine of biotrophy which, of itself, helps to make clearer the terms of the problem by the conception of a failure of nutritional energy with a consequent limitation of the durability of the organism and of the length of life. In applying this doctrine to certain pathological changes it is said that the overgrowth of interstitial neuroglial tissue, when the nerve elements decay, is in consequence of the fact that the two elements have "a common but inverse vitality"; when the nutritional energy fails to maintain the growth of both the more highly specialized tissue ceases to live, while the less specialized tends to overgrow with the tendency of the former to decay. It is explained that these "tendencies are in the opposite direction, but they seem to be coincident results of the same vital condition."

In the many well-known conditions of constitutional weakness and instability, it is easy to understand the nutritional failure to develop normal growth and efficiency of function, or to maintain them, and the consequent recession of the developmental processes, even to the cessation of life. The doctrine of dissolution as characterizing the many conditions of such recessions is clearly consistent. When biological conceptions are invoked, it is also easy to comprehend the general principles of development whereby, through physiological reactions of the organism, there are adaptations and modifications of characters due to changes of environment and favorable to life and health; it is intelligible that through use higher types of characters may be produced, or through disuse recessions to more primitive types, under the causative influences of the environment, and all this may be within the physiological limits of the organism as expressions of the processes of life. In the domain of biology it is, no doubt, helpful for descriptive purposes to conceive of the developmental forces as acting in an inverse direction, producing the effects of reversals and regressions. But when this latter conception is applied to pathological conditions, it is in harmony with our prevailing modes of thought in medicine that there is conceived to be an attack, as of some harmful agency, upon the living organism; a pathological process of degeneration is supposed to ensue which is a regressive process of decay, and this implies its active going backward against the normal tendency of the nutritional energy to maintain life and growth. As a further explaining principle the conditions of acquired or inherited defect are conceived, and a process of degeneration of which "heredity" is the motive force; thus the evolutionary and developmental forces turn against

themselves, and working in the inverse direction, produce decay. Here is seen the all-pervading disposition to seek an immediate cause for every effect, and it is easy to describe agencies and processes. When the stamp of "degeneracy" is fixed upon a fated organism we commonly think of its possessor as a "degenerate" descending to inevitable doom.

Is it not evident that there is a misleading ambiguity in the prevailing usage of the conception of "processes"? It is necessary to the notion of a process that there is a passing over of one set of phenomena into another, and this constitutes a change.¹⁵ A "process" is constituted of a series of such changes when one stage or aspect of the process necessarily succeeds upon another. The action of a causative force or stimulus is essential to the change as in the biological processes. The requirements of the conception of two coincident processes appear in the principle of the psycho-physical parallelism in the relation of mind and body. It being the general fact that certain changes in those brain and nerve processes with which consciousness is associated are always accompanied by changes in consciousness, and the converse being true also, then certain other scientific principles are involved: (1) The principle of *equal continuity*, with no breaks in either series of changes, — if one series is continuous, the other must be continuous also; (2) the principle of *uniformity*, — when certain phenomena in each series in brain-process and conscious state are essentially associated, then the concomitance of those terms may be looked for on all other occasions; (3) the principle must be a *universal* one, — whenever we find a series of phenomena in either of the parallel trains of events the principle of parallelism has its application. Structure and function must exist before there can be any disease; the phenomena of life represent the supreme process in animate nature; the phenomena of disease and degenerations appear as the results of discontinuous interferences with the life-processes in which "normal function is acting under abnormal conditions"; the assumption of a "disease-process," or of a "pathological process" in the same sense, fails to meet the essential requirements of a "process," — it is certainly not comparable with the life-process. If we must speak, for convenience, of "pathological process" and "degenerative process," the terms should be used only in a very narrow sense of comparatively transient interferences, or in the sense of referring to normal function acting pathologically.¹⁶

To the inquiring mind the contradictory presentation of these matters is confusing and creates difficulty. The subjects are, in their nature, complex, and our knowledge is limited, but much ambiguity is undoubtedly due to the lack of precision in the statement of the terms of the

¹⁵ Baldwin, J. M. Development and Evolution, 1902.

¹⁶ The writer's views of the inadequacy and misleading influence of the "disease process" conception as a question in psychiatry, was first presented to the American Medical Psychology Association at its meeting in Washington in 1902 in a paper on the principles of mental pathology and the nature of mental symptoms.

problems. One of the most common obstacles to clear thinking appears to arise out of the fact that for every predicate implying action we have to think of an actor or causative agency, and our minds habitually conceive of some form of personification of such an agent as possessing motor and motive attributes. Thus we think of life and death, and artists picture them, in human forms; we are prone to dualistic conceptions and the mind delights in such paradoxical phrases as, there can be no death without life; no disease without health; no evil without good. The use of the active predicate abbreviates expression, and enlivens speech. Professor Sanford,¹⁷ discussing the influence of physics on psychology, notes the fact that, as the result of man's long primitive practice, his habits of thought are objective, and the language he uses is saturated with physical connotations and metaphors. It is not easy for even the best of us, he says, to keep clear of this inveterate physical-mindedness and the subtle suggestions of language; we help out our thinking by material figures and feel a sort of dumb compulsion to make our psychological theories accord with physical requirements. Ebbinghaus is quoted as describing the older psychology as distinctly "mechanistic," many analogies from familiar material processes being used in the exposition of mental phenomena. In regard to essentials, Professor Sanford thinks it may be said that psychology has outgrown this method. But, turning to our own field of the medical sciences, the ruling tendency of our thought and language leads to the conceptions of "disease" and "process," for example, in terms implying immediate causative agents. The familiar conceptions of a process of anabolism and a contending process of katabolism in the cell are treated as the analogues of the life-process and death-process. The analogy is extended to include in this conception the fact that in the whole compound organism the anabolic processes overbalance the katabolic till middle life, when the two processes are more nearly in equilibrium, and that thereafter katabolism predominates more and more in the normal decline of old age. It is held that in the broadest sense the process of senescence begins with the beginning of life in a progressive diminution of the power of growth; and with the progressive waning of the vital powers the leading somatic changes accompanying old age are atrophic and degenerative. The same conception concerning the anabolic and katabolic processes is equally legitimate concerning the idea that an inherent tendency to degeneration is transmissible; the inherited constitutional weakness and diminution of vitality may be interpreted as belonging to the series of changes which imply a process of dying continuing through several generations.

There appears, through all these reasonings, the prevailing method of thinking in terms of "processes." The inquirer is moved to ask whether the normal processes of anabolism and katabolism

are not both essential to the maintenance of a health-perfect cell and both, therefore, parts of the normal life-process. We do not think of the most healthily active cell as one most vigorously dying. If we consider the physicochemical changes in the cell inclusively as a process of metabolism, it is consistent to think of the normal building up and breaking down of complex compounds in growth, work and repair as harmonious, and not antagonistic, operations. Hering separates assimilation as only a qualitative chemical change from growth as quantitative, and in like manner dissimilation from atrophy. As to the transformations in the cells and the overwhelming number of substances excreted from them, little is known of the processes by which these are derived; but many products are formed in both the ascending and descending portions of the metabolic series. Disordered and imperfect adjustments of the molecular arrangements of living substance may affect and arrest both anabolism and katabolism; defect of the latter and not its predominance can be conceived as a cause of the death of the cell.

In physiological theory the distinction is made between death of the tissues and somatic death; in the former, it is reasoned that constantly throughout life the molecules of living matter are being disintegrated and whole cells die and are cast away,—and that life and death are concomitant; in the latter, death occurs when one or more of the organic functions is so disturbed that the harmonious exercise of all the functions becomes impossible. This distinction has been referred to, and further inquiries are suggested here. In respect to the death of the tissues, the "unit cell" being an organism of high complexity as to its structure and function, and its life-process, is not failure of this life-process of the co-operative adjustments within the cell truly analogous to the failure of life, or somatic death, in the whole compound organism? In this connection the question again arises as to the concomitance of the processes of life and death,—the latter being theoretically analogous to the constant disintegration of living matter. Hering's idea that assimilation and dissimilation are distinctly separate from growth and atrophy permits the former to be regarded as one intimately combined and normal metabolic process in a working cell, having no theoretical significance except as wholly contributing to the maintenance of the function of a health-perfect cell. The daily shrinkage of the working and fatigued cell may be regularly made up by rest and nutrition; this is not atrophy, either simple or degenerative, for the continuity of cell-life may be unimpaired and only the labile molecular inclusions be changed by normal use which promotes the health of the cell. On the other hand, the function of growth, being of a more primitive type, would appear to contain the explaining principle of the life-process as contrasted with the work-process. Consistent with this appears to be the sharp differentiation made by Adam between cells which have the habit of growth and

¹⁷ Sanford, E. C.: *Psychology and Physics*, The Psych. Rev., vol. x, 1903

those which have the habit of work; these two functions cannot be exercised by the same cell at the same time, and a normal working cell may revert to the type of a vegetative cell. This implies that cells of the primitive type having only the function of growth, their "work" (in the common usage of the word) is without external manifestations of energy; but that the function of work, which is the power to store potential energy within and to produce kinetic energy in external work, belongs to the highly specialized cell as an acquired character which it may lose. This being true we may understand that assimilation and dissimilation, in the limited sense employed by Hering, constitute a special kind of inclusive metabolic process different from the molecular changes, perhaps less complex, productive only of growth. It is not conclusive that katabolism typically represents destruction of life though it means changes of substance in which life exists. These considerations suggest questions that are not in harmony with the generally accepted theory of life and death as concomitant processes based upon an assumed analogy to the physiological processes of the healthy, living cell.

This inquiry is intended only to consider some examples of current theories with the question whether they can be resolved into more simple conceptions. The life-process being conceived as the one supreme "process" in living organisms, this implies its maintenance by causative forces; assuming each individual to be endowed with a given vital durability, determined by antecedent conditions and subject to modifications due to favoring or adverse influences, the life-process reaches its possible attainments and finally fails in the struggle for existence. Injury, interference with normal function, overuse and disuse, disease and the causes of the changes of senility present alike adverse influences which the organism fails to overcome. We must speak of disease and use its meaning as referring to results in diseased parts, organs or tissues; and we may commonly think of the word as implying a combination of disorders of functional activities which may or may not be associated with ascertainable structural changes. But it should be remembered that we are thinking of a patient and not a "disease." There is no disease-process; no enervative forces exist in nature that induce and carry on processes of degeneration and decay; gradual failure is the summation of the failures of community work due to the complexity of the organism, each organ being subject to the harmful influences of the functional failure of other members of the community. There may be deterioration of function, and degeneration of structure in the sense of failure to maintain it; there may be also regressions or rather recessions of results, but no active pathological "process" of going backward in the structural reductions called "degenerative." These considerations do not support the idea of a "physiological old age" based upon the conception of a normal process of degeneration or decay as though the results of

senile conditions in structural changes are different from disease. This doctrine of natural decay and death makes great trouble in dealing with senile conditions in medico-legal cases; and in like cases concerning degeneracy, in earlier life the most contradictory and confusing notions prevail. They are not in harmony with practical experience. This is largely due to the adoption in psychiatry of generalizations in regard to heredity not yet warranted by the science of biology. The morphological ideas in the prevailing pathological conceptions, and the descriptive terms employed, have undoubtedly obstructed the progress of psychiatry. From all such preconceptions the psychiatrist should be wholly emancipated.

A functional conception of pathology is not in conflict with a pathological conception in the sense of the long-used distinction between functional and organic diseases. The objection to this is not lessened, but the fault is not with function. Life and the science of physiology are first; function and all that pertains to it are primary facts of the activities of normal life. Much disharmony in the conceptions of pathology has been due to the setting up of ideas of "organic diseases" as the chief factors in pathology, and the minimizing of function as worthy of serious scientific consideration. Our conceptions of function are uncomplicated as relating simply to the modes of action of the several parts of the organism; but we must think of organic disease in two ways, of changes of structure in results and of changes of action in "process." The functional factors are necessary to organic disease, and their distinction and true relation should be discovered in their combination. The organic changes of disease are the sequels of interferences with the prime process of normal life.

PHYSIOLOGY AND ITS RELATION TO PSYCHOLOGY.

Physiology acknowledges its debt to Johannes Müller, who mastered the two great sciences, morphology and physiology, and was a teacher of pathology. He took an active interest in psychology, regarding physiology by empirical methods as essential to advancement. After Müller's death, nearly fifty years ago, the fields of his scientific work were divided by the specializations through which the present marvelous advancement has been gained. Physiological chemistry became independent of physiology; and physiological psychology developed on the lines of psycho-physical experiment. It was then that mental physiology should have made its union with mental pathology. It is easy to see that psychologists tried to accomplish this by its attempts to find a morphological basis for its investigations through the experimental method, but the field for this was limited. Psychiatry, under like limitations, by its morphological attitude met the invitations of psychology with inherited distrust of a functional pathology. Psychology was turned upon itself, and also, much of its own choice, sought and found open ways back into the attractive regions of the in-

vestigation of psychical function and philosophy. The later phase of psychiatric interest in experimentation has been mentioned, and is full of promise, but such movements require years of time. The method of exhaustive study of the clinical expression of psychical reactions through speech and behavior, and the use of experimental tests which bring out individual characteristics and their variations, are gaining a share, which must increase, of the attention and interest heretofore centered in the pathological laboratory. This is a new and definite revelation of a tendency toward the study of a functional conception of pathology in psychiatry.

Psychology is still kept apart, however, from the practical study of mental pathology; this is probably, in part, its own fault: although some students of psychology have shown the requisite interest, there is a lamentable want of opportunity. What would really be the most promising interest in psychiatry should be found in the establishment, in hospitals for the insane, of true experimental psychology, with physiological methods applied clinically, according to the principle of using instruments of precision in other clinical work.¹⁸ The observer of these clinical manifestations, trained both as a psychologist and physiologist, would find many new variations of phenomena not seen in the normal subject. A hospital for the treatment of mental disorders is a laboratory of itself where nature makes experiments in the excitation, suppression and combination of naturally correlated psychical and physical reactions, giving many clearer displays of their nature, both by their intensification and absence.

Mental diseases are peculiarly and essentially constituted of mental symptoms; the study of their phenomena must refer them to mental physiology, for the laws governing vital phenomena under abnormal conditions are not different from those of normal life. The study of mental physiology under pathological conditions should be helpful for both psychology and psychiatry.

This inquiry being assumed to be free from all preconceptions as the true nature and place of mental pathology, and as to forms and names of mental diseases, it may be turned to an examination of the relations of psychology, or mental physiology, to all of the associated reactions of the physical organism. This is the necessary basis of pathological physiology for psychiatry. Approaching the subject newly from this point of view the physician should seek to inform himself concerning at least the immediate facts of mental function and the accepted postulates of psychology. But in preparation for such a study it should be recognized that mental physiology is included in general physiology as concerning a

part of the vital activities of the living organism; also that certain general modes of action in the body always have a part in mental function. Some of the symptom-factors of mental disorder have their genesis in conditions that affect primarily other parts of the organism than the brain. General physiology therefore claims the attention of the psychiatrist to certain essential principles whose importance can only be indicated here by mentioning some of those of immediate interest; the purpose is to present some of the physiological reasons for the proposition that the problem of psychiatry lies in the functional psychoses.

A distinctive feature of modern biology is the fundamental conception of a living body as a physical mechanism (Huxley); underlying all the phenomena of the animal organism is the reflex action of the nervous system, and physiologists generally agree to consider every action as aroused by some cause or stimulus (Sedgwick); under the biological conception man is an organism for reacting on impressions (James). The nervous and mental mechanisms being regarded as constituted of three minor ones, their action appears in a sensory—a central or transformation—and a motor process; in the central process part of the work done by the nervous system leads to consciousness; the response to a stimulus may be a muscular contraction, a secretion in a gland, a vascular change, or even a trophic or metabolic influence,—all pertaining to the centrifugal system. While reflex action is not conscious action, one may be conscious of the act, and in many cases conscious changes precede, accompany or occasion the change. The most important reflex of all is commonly ignored, viz., that which provides for the constant readjustment of the parts of the system to each other, by virtue of which the entire mechanism is receptive even to minimal stimuli. This may be termed the *neuro-equilibrium reflex*. The tone of the nervous system is this wonderfully complex adjustment of inhibition and stimulation. Every metabolic process in all the nerve cells exerts its influence on the entire nervous system. One of the most remarkable reflex associations is that between vaso-motor alterations and the seat of the emotion, which are thus intimately involved with the viscera and vessels in their minute connection with the sympathetic system. This association has a most important influence in the mental sphere, though beyond this fact little is yet known of the physiological basis of these reactions.¹⁹

The intimate connection of mental states and the physical reactions of the whole body is well recognized by both physiologists and psychologists; it is of fundamental importance in psychiatry. Lombard²⁰ describes the cells of the central nervous system, during waking hours, as continually under the influence of a shower of weak nervous impulses, coming from the sensory organs all over the body; moreover, activity of brain-cells, especially emotional forms of activity, leads to an overflow of nervous impulses to the spinal cord and an increased irritability, or, if stronger, excitation of motor nerve-cells. There is a constant inflow from the environment of a vast number of excitations ordinarily disregarded by the mind but all the time influencing the nerve-cells; the effect of this multitude of afferent stimuli, in spite of their feebleness, is to cause the motor cells to continually send delicate motor stimuli to the muscles and to keep them in the state of

¹⁸ For an account of the beginning of the present laboratory methods, both psychological and chemical, at the McLean Hospital in 1889, see "Les Laboratoires de Psychologie en Amérique," by E. B. Delabarre, *l'Année Psychologique*, 1895; also "Laboratory of the McLean Hospital," by G. Stansley Hall, *Ann. Journ. Insanity*, 1895. The subsequent development of the pathological laboratory and the clinical methods,—of the laboratory for pathological chemistry in 1900,—and of that for pathological physiology and psychological experiment in 1904, constitute a true psychiatric clinic of a special character, designed from the outset for the investigation of the functional conditions of mental disorder.

¹⁹ Cf. Baldwin's *Diet. of Philosophy and Psychology*.

²⁰ Lombard, W. P.: *The General Physiology of Muscle and Nerve*. *Am. Text Book of Phys.*, vol. 2, p. 143.

slight but continued contraction or tension of *musculotonus*. In these mechanisms is the seat of the kinesthetic sensations and the functional alterations that play so essential a part in contributing to the well-known symptom-factors of the "sense of effort" and "inadequacy" and motor "retardation" and "excitation."

Some of the physiologists have given much study to the relation of mental and physical states. Sherrington's "discussion of common and organic sensation and the contributing cutaneous sensations has an extraordinary interest for psychiatry. Common sensation is understood to mean that sum of sensations referred not to external agents but to the processes of the animal body, and these sensations possess strong affective tone. Total common sensation is the result of many component sensations, and those that arise in internal organs and viscera contribute a great deal to the total sum. Affective tone is the constant accompaniment of sensation; every form of common sensation is based on perception of an altered condition of the body itself. In connection with this comes the fact that all forms of common sensation present significantly pre-eminent attributes of physical pleasure or physical pain; and all are linked closely to emotion.

The elaborate researches of many observers in recent years concerning the nature of the muscular sense, the senses of touch, pain and temperature, and their special mechanisms, strengthen the common fact that their sum contributes to the effects upon mental feeling-tone. They are in their nature productive in part of the organic sensations. "Habit" has studied, more than anyone else, the psychology of the emotions and the logic of their mental and physical reactions; he describes the presentations in the conscious mind of organic sense as constituting a vast aggregate of impressions arising from within the organism and continually flowing towards the superior nervous system; it is this region of subject consciousness that gives the consciousness of being, the sense of personality. The sensations from the special senses are intermittent of high intensity, and small in volume compared with the voluminous though faint, continuous, and all-pervading commotion produced by the organic sensations. These are intense enough, however, to be susceptible in health of psychical interpretation as a sense of well-being; from their disorders and intensification, come the sense of ill-being. These are the long recognized changes of coenesthesia. Professor James has shown the intimate relation of the emotional tone to bodily states; and Professor Ladd makes clear the usefulness to psychiatry of a study of the affections and emotions in their relations to the train of ideas, and to the different bodily organs; also the reflex effect of the changes in these organs upon both the feelings and the ideas.

Underlying all these physiological phenomena of the living organism is the primary attribute of irritability. All the functional phenomena being influenced, within normal limits, by changes of irritability in the central, peripheral, sensory and motor mechanisms, and these changes being dependent upon the processes of nutrition and metabolism, and upon conditions of use and disuse, rest and fatigue, etc., the alterations of functional efficiency in the associated reactions of mind and body make the study of cellular physiology imperative for psychiatry. Some of the most commonly observed and characteristic symptoms in mental diseases may be referred to such functional disorders in the physical organism.

The healthy organism being fully constituted in structure and function for its work, when put in use begins immediately to be subject to modes of action which are the effects of its own activities. In other words, the living organism acquires functional characteristics as the immediate effects of use. Some of the common physiological laws have a special importance here because they govern the work of the physical mechanism and therefore of all correlated mental reactions, not only in health, but in disease as long as any functional activity continues.

(1) Association and habit are fundamental in mental life; in respect to the association of ideas it is not the ideas that associate but the elementary processes of which the ideas are composed; on the physical side the law reduces to the law of habit (Titchener). Memory is an associative process; mental reactions (including perceptions, ideas, emotions) are associated with their physical correlatives and motor consequences. Habit is closely related; it is the functional disposition to repeat organic processes. This law of association and habit applies to "organic memory", thus "associative memory" is fundamental in and unites both psychical and physical reactions.

(2) Inhibition. The animal organism has a motor character. All sensations and mental states are motor; the entire neuro-muscular organism, mental and motor, acts primarily as a whole governed by the laws of association, and this is subject to control. "The phenomena of nervous life are the outcome of a contest between what we may call inhibitory and exciting or augmenting forces" (Lyster). It is conceivable that all nerve centers are normally at all times subject to continuous control or inhibition, and are maintained in a condition of mobile equilibrium by the opposition of this inhibition to their own inherent tendency to discharge (Mermet).

Inhibition is an action which obstructs or impedes another action, and which weakens or arrests it if it was already in action (Osborne).

Voluntary action is at all times the resultant of the compounding of our impulses with our inhibitions (James). "The inhibition of a mental process is always the result of the setting in of some other mental process" (McDougall). It may be said as a physiological conception that in living substance there are conditions of cohesion and inertia by virtue of the anabolic tendency of its physical and chemical elements; this may be called *physiological inhibition*; and it is the primary factor in the mobile equilibrium conservatively holding the balance against the tendency to discharge induced by constant external stimulation. The psychological conception of the essential physical fact is that one mental process inhibits another, that is, that as a will-impulse implies a motor process which may inhibit or excite and again excite other mental or neural process, thus that the called *voluntary inhibition*. The great importance of the study of inhibition which is only indicated here lies in its holding an equal and counter

balancing place in mental and physical processes.

(3) Energy of muscle and nerve. This refers to the principle of the storage and discharge of energy, and the biological theory that functional activity of a specialized tissue depends primarily upon chemical changes in its individual cells. The fundamental idea is that in the resting state the cell elaborates highly complex compounds and that these break down to yield the energy by which the cell does its work; discharge and restoration of energy is common to both nervous and muscular elements. Hughlings Jackson characterizes the animal organism as "an apparatus for the storage and expenditure of nerve force." These principles are of essential importance in the study of mental disorders. Inasmuch as functional efficiency must be taken as measure of the available energy, it should be expected that exhausting influences would reduce functional power. Such reductions characterize all forms of the functional psychoses, and the variations of their symptoms are consistent with this principle.

(4) Physiological use and fatigue. — waste and repair. The law of use includes the wholesome effects of those just cited; normal use develops functional activity and strengthens power, while disuse weakens function. Overuse begets fatigue, and normal fatigue presents mental as well as physical effects. *Physiological fatigue* may be continued beyond the point of regular recovery by rest and nutrition; it then becomes the *pathological fatigue* of nervous exhaustion or neurasthenia with the characteristic symptom-groups. A functional conception of the significance of these groups of mental and physical symptoms should stimulate not only such a precise observation of them as is needed to constitute "disease-forms" and mature types, but should lead to their being analyzed and traced to their functional sources in the whole organism in accordance with the principles of general pathology. This method reveals the genesis in physical states of some of the most characteristic mental manifestations. Beginning with the fundamental attribute of irritability, for example, wide variations occur within normal limits, but more striking and significant changes appear in all forms of pathological fatigue, and the functional psychoses: the irritable weakness and languor of neurasthenia, and the psychomotor excitations, retardations and "confusions" of melancholia and mania are examples. The study of these alterations of irritability involves the whole problem of reflex-action and the mechanism of responses to stimulation of both mental and physical functions. It is to be recognized also that all of these reactions contribute to the sensory returns from the whole organism. — from the viscera, muscles, and even the special senses including the special dermal sensations, to the central nervous system, constituting the kinesthetic and organic sensations. In mental physiology a functional conception of these reactions reveals their importance for an understanding of the genesis of emotional changes and

the alterations of the affective tone in states of persistent mental depression. The sense of well-being and ill-being depends upon these variations. Most important of all, because so completely neglected in psychiatry, are the bluntings and losses of organic sensations and the consequent effects upon the feeling-tone and ideation; in this regard attention should be called, especially, to a remarkable fact well-established in physiology and psychology. It is evident that the normal irritability of nerve and muscle requires the maintenance of a certain chemical constitution; slight variations from this, temporary or continuous, alter or may destroy the irritability. Further, it is noticeable in most cases that the first step toward deterioration is a rise of irritability; the cause being increased or continued, sooner or later exhaustion supervenes, the irritability lessens and is finally lost.²³ These functional reductions of sensibility, in a wide range of varied degrees and combinations, are constant symptom factors in psychiatry.

The relation of mental physiology having an essential importance for psychiatry there should be a first reference of all mental symptoms to their functional sources in the organism as far as possible with respect to their correlation and association with alterations of bodily functions. By the genetic method study should begin with the minor changes from normal action; these alterations show intensifications and losses of function, and symptom-groups are modified by their varied combinations.

VAGINAPEXY.

BY W. P. GRAVES, M.D., BOSTON.

THE encouraging results of the operation for procidentia devised by Dr. W. H. Baker and named by him vaginapexy have led us to make a preliminary report of its progress.

Vaginapexy, as the name implies, denotes an operation for stitching the vagina to the abdominal wall and is used in cases of extreme vaginal relaxation, such as prolapse, incomplete and complete procidentia and advanced cystocele. The idea of attaching the vagina to the abdominal wall, although independently worked out by Dr. Baker, cannot be claimed as a new procedure for it has been suggested, and, to some extent used, since 1893, and during the past year employed with success by Dr. Polk of New York, also working independently, and described by him at a meeting of the Practitioners' Society in New York, May 5, 1905.¹ The operation developed by Dr. Polk at about the time that Dr. Baker was working on his operation consisted essentially of the same fundamental principle, namely, the attaching of the vagina to the abdominal wall, and was given by him the Greek name

colpo-orrhaphy, synonymous, of course, with the Latin term *vaginapexy*, adopted by Dr. Baker. The two operations have differed in several features in the process of their parallel development, and for that reason *vaginapexy* is here described as an independent operation.

In the practice of gynecological plastic surgery the treatment of prolapse, procidentia and cystocele by numerous and ingeniously devised operations has always been uncertain and often discouraging. In the more severe cases a complete cure could never be truthfully, promised and even in moderate cases it was often necessary to do repeated operations in order to meet recurrences of the original condition. It has been a not uncommon circumstance to find patients with distressing forms of procidentia who had suffered for years because they had been told by their physician that their trouble was surgically incurable. The operation devised by Dr. Baker has not only completely revolutionized our surgical treatment of these cases, but has encouraged us to give a far more hopeful prognosis than could have been given under the surgical treatment formerly used.

It seems to me that the reason that former operations for procidentia, prolapse and cystocele were only partially successful was due to the lack of appreciation of the mechanical principle, essentially needed to repair these conditions. Severe cystocele, procidentia and prolapse are phases of one and the same anatomical lesion, namely, loss of fascial support made by the attachment of the vagina to the rami of the pubes. This attachment of the vagina is, in my opinion, far the most important element in maintaining the integrity of the position of the female pelvic organs. There is no doubt that the uterus is maintained largely in its normal horizontal plane in the pelvis by this vaginal attachment, and the same can be said of the lower portion of the bladder. Prolapse, procidentia and the accompanying cystocele are invariably the result of lack of this vaginal support, and conversely it follows that the rational cure for these conditions must be the restoration of this same vaginal support.

If this premise be accepted as true it is obvious that the first object in devising a cure for the conditions mentioned is to select some method of restoring the vaginal support of the pelvic organs. It has proved an uncertain procedure to attempt to attach the vagina to the rami of the pubes, although in an early operation invented by Dr. Baker and used by him for many years the vagina was sewed by deep stitches to the periosteum of the pubes. This in many cases resulted successfully, but, as can be imagined, even at the best such an attachment could hardly be strong enough to withstand permanently the powerful abdominal pressure from above. Disregarding then the rami of the pubes as fixed points from which to suspend the vagina it is manifest that the only available point of fixation is the anterior abdominal wall.

The fixation of the vagina to the anterior ab-

dominal wall after the removal of the uterus and appendages is a plausible operation, but this operation with the appendages and uterus *in situ* would at first seem to be an unsurgical and well nigh impossible procedure. It can at once be seen that by seizing the vault of the vagina from the abdominal side and drawing it up to the abdominal wall the uterus is completely anteverted and would suggest symptoms such as pressure on the bladder and tension on the abdominal wall or on the vagina, to say nothing of the possible dangers in a future conception.

Although a year's time is possibly too short a period in which to make the most definite claims with regard to the results in such an operation as this, yet it is certainly long enough to give correct information with regard to most of the above mentioned symptoms. In not one single case, even where there has been extreme anteversion or much tension on the vagina and abdominal wall, have there been any bladder symptoms whatsoever, but, on the contrary, cases in which there were distressing bladder symptoms due to the accompanying cystocele, have been completely relieved in a comparatively short time. It may also be said that the anteversion itself disappears in a very few weeks and examination shows the uterus to have settled into its normal position with regard to its longitudinal axis. It may be said, too, that the deep depression which is often seen in the abdomen following one of these operations usually completely disappears before the patient leaves the hospital and in no instance have any symptoms which might be referred to the tense drawing of the vagina been complained of. With regard to the possible dangers which might ensue in view of a future conception we are obliged to be more guarded in our statement. None of our cases have become pregnant following operation. Of course, as a rule, the majority of cases which require *vaginapexy* are either near the close of or past the child-bearing period. In younger women the presence of procidentia almost always implies at least two or more previous conceptions, so that it is usually no hardship for such women to be deprived of the privilege of having more children. There must, of course, be a certain possibility of trouble following fixation of the vagina in the case of pregnancy and in all cases where that might be possible we have advised our patients to avoid further child-bearing.

Indications for operation: The indications for *vaginapexy* are present in all cases where the vaginal attachment to the rami of the pubes has completely or incompletely given way and would, therefore, imply conditions of marked prolapse, complete or incomplete procidentia with accompanying cystocele. It may be well in this connection to define clearly the manner in which the terms "prolapse" and "procidentia" are used. Prolapse includes those cases where the uterus has dropped down from its normal horizontal plane in the pelvis, but has not dropped far enough to appear at the vaginal outlet. Partial procidentia includes those cases where the os appears at the

vaginal outlet and protrudes from it. Complete procidentia signifies that the uterus may be forced by abdominal pressure entirely beyond the vaginal outlet. The following then may be formulated: Vaginapexy is indicated in all cases of incomplete or complete procidentia; in those cases of prolapse where the ordinary suspension or fixation of the uterus does not draw the vagina firmly up into the pelvis; and, finally, in those cases of cystocele where the lateral attachments of the vagina have given way. It will thus be seen that the operation is especially valuable for the cure of the worst forms of cystocele and goes far toward solving the difficult problem of curing this condition. It is, of course, true that many cases of cystocele occur where the uterus still maintains its normal level in the pelvis and that the protrusion of the bladder into the vagina is simply a thinning out of the anterior vaginal wall without the loss of the lateral supports. This class of cases can nearly always be cured by some one of the numerous forms of anterior colporrhaphy, if it be borne in mind continually that the real support in an anterior colporrhaphy should be taken from the lateral attachments of the vagina.

It must be remembered that in all cases where vaginapexy is indicated one or more operations must always be done in conjunction with it. Dr. Polk advocates a complete hysterectomy in every case of procidentia. This is not, it seems to me, necessary excepting where the body of the uterus itself is extremely heavy and burdensome, either from a long standing congestion and gland hypertrophy or from the presence of fibroids or malignant disease. In the majority of cases of procidentia we find that the fundus of the uterus is undergoing atrophy, that the cervix itself is long, attenuated, sometimes to the extent of four or five inches, and that the cervix terminates, in its exposed part, in a greatly hypertrophied and ulcerated mass. In other words the chief weight of the uterus is not at the fundus, but in the hypertrophied, elongated cervix. In my own cases it has seemed to me advantageous instead of performing a hysterectomy to amputate the cervix and to carry this amputation as far up toward the body of the uterus as it is possible to go without opening the abdominal cavity. This leaves the small atrophied fundus of the uterus to act as a firm cap to the vault of the vagina, and its weight is so inconsiderable as not to affect the future outcome of the operation. The amputation of the cervix, if properly performed, involves almost no risk to the patient's life such as is incurred in a complete hysterectomy, and this consideration is of no small importance in the case of elderly or even aged women who often present the most distressing forms of procidentia.

The amputation of the cervix, or hysterectomy, if deemed advisable, is performed first; the patient is then put in the Trendelenburg position and the operation of vaginapexy is done. This completes the first step of the treatment and the patient should be allowed to recover completely from these two operations. She is then allowed

to be up and about on her feet for several days. At the end of this time it can be seen how completely the vagina is held up and how much slack is to be removed in the plastic operation now necessary. The patient is again etherized and placed in the perineal position. In our first operations we usually found it necessary to perform an anterior colporrhaphy and then do a deep and thorough perineorrhaphy. In our later operations, where undoubtedly the vagina has been somewhat more boldly attached to the abdominal wall, it has usually not been necessary to perform an anterior colporrhaphy, but instead an extensive Emmet's perineorrhaphy, where the denuded lateral sulci are carried well up toward the cervix and high up on the lateral walls so that when the lateral stitches are tied the caliber of the vagina is very much lessened and a thick, firm, perineal support is gained. The vaginal outlet is made somewhat smaller than in the ordinary operation of perineorrhaphy and the denudation of the external perineum carried somewhat further out toward the buttock in order to give added strength and thickness to the perineum.

The operation of vaginapexy has been done 19 times at the Free Hospital for Women and at Dr. Baker's Private Hospital. Of these Dr. Baker has done 8, Dr. Pease, 1, and I have done 10. These operations have been done at intervals for more than a year and though it is too early to claim a permanent cure of those more recently done, the results as carefully observed are extremely satisfactory and far exceed in value for a proportionate length of time the results of operations formerly used for the relief of prolapse, procidentia and cystocele. In only one case has there been a recurrence, and in this case which was one of the earliest cases done, the vagina was stitched only to the peritoneum of the abdominal wall in the manner of a ventro-suspension. The operation was performed a second time and the stitches carried through the fascia instead of the peritoneum in the manner of ventro-fixation. A perfect result followed. This procedure has been employed in all of the other cases and in none of them at the present time has there been the least suggestion of a recurrence. It is, of course, necessary to avoid too great enthusiasm in the early stages of operative experimental work, and it is for that reason that this paper is presented only as a preliminary report. It can, however, be said that we now feel the greatest encouragement in undertaking the surgical treatment of the distressing condition of procidentia and our prognosis to the patient can be made with far greater hope and confidence of a permanent cure than was possible from the employment of former surgical measures.

The technique of the operation is as follows: The patient is placed in the Trendelenburg position and a small median abdominal incision made. The intestines are then packed away with gauze in order thoroughly to expose the posterior cul-de-sac. Beginning first on the right side, a point is selected a little posterior and external to the

peritoneal reflexion of the posterior cul-de-sac from the wall of the uterus. This point is then seized with the bullet forceps, the forceps being carried deep enough in order actually to seize the wall of the vault of the vagina. In order to ascertain whether or not the wall of the vagina is included within the teeth of the bullet forceps it is a safe plan to have an assistant insert his finger in the vagina so that he can give information as to whether the vagina is really being drawn up by the traction of the bullet forceps. When it is found that the vagina is firmly grasped, a silk suture, preferably No. 10 braided silk, is passed through the tissue to take the place of the bullet forceps. The suture is then passed up through the peritoneum, rectus muscle and fascia of the abdominal wall about one half to three quarters of an inch from the incision. It is then passed back again into the abdominal cavity and included with the other end of the suture in a pair of snaps. The same procedure is then carried out on the left side and the two sutures tied, drawing the vagina firmly up to the anterior abdominal wall and completely anteverting the uterus, the knots being thus left within the abdominal cavity. The abdominal incision is then closed with great care, in layers. In passing the suture through the floor of Douglas's pouch I have found it advantageous to employ the stitch devised by Mr. Max Brodel for the suspension of prolapsed kidneys as it gives far greater tensile strength. This stitch is depicted in the accompanying drawing. It is, of course, essential to avoid carrying the suture through into the vaginal cavity.

CONTRACTILE PROCESSES IN THE LUNG AS A RESULT OF PHTHISIS, WITH REFERENCE ESPECIALLY TO THEIR PRODUCTION OF PERMANENT DEXTROCARDIA.*

BY HENRY B. DUNHAM, M.D.,

The Massachusetts State Sanatorium, Rutland, Mass.

AFTER a careful search through numerous published reports, I have been able to collect about twenty cases of acquired dextrocardia as the result of a chronic contractile pulmonary tuberculosis. Although only able to find record of twenty cases of acquired dextrocardia of the variety described (the left side of the chest appearing sound, or practically so), I think that many unreported cases must have occurred.

The question as to whether the heart is chiefly pulled or pushed over, although of small consequence, is interesting as a pathological study. In Albutt's system, Vol. V, p. 207, Dr. Percy Kidd says: "In the fibroid or contractile form of pulmonary tuberculosis signs of excavation are generally to be recognized at one apex, associated with much dullness over the upper lobe or over the whole lung, together with displacement of neighboring organs. When the right lung is

contracted the heart is drawn over and may lie wholly to the right of the middle line. In extreme contractile cases the opposite lung is always considerably enlarged and may pass beyond the middle line of the sternum into the opposite half of the thoracic cavity."

The above description fits all of the cases, but does not explain why there should be actual enlargement of the left half of the thorax as in a true compensatory emphysema.

In both my cases mensuration of the chest early in the course of the disease and then after the displacement shows that bulging of the ribs on the left side has surely occurred. The circumference of the thorax on the left side is not only greater than the right, but is greater during both inspiration and expiration than was formerly the case. The chest expansion, however, is much diminished, being about one half of the former measurement.

A fairly accurate idea of the period of time required for complete transposition of the heart in these cases is of some value, but in all cases previously reported the displacement was already complete when the patient came under observation. In all cases the right lung was the site of the tuberculosis, which always seemed to be of a chronic fibroid type with sclerosis of the lung tissue and bronchiectasis. The left lung seemed always either sound or very slightly affected. All of the observers lay great stress upon the contraction and sclerosis of the right lung and said either nothing or very little of the compensatory hypertrophy of the left lung as a factor in the causation of the malposition. An x-ray examination of my two patients' chests shows a decided augmentation in volume of the left lung. There is perfect transparency over the normal site of the heart, and upon percussion good resonance is elicited over the same area. Of all the recorded cases only one was reported as having been examined with the assistance of the x-ray, and in this instance (Barbier) there was found "augmented volume" of the left lung. This feature strikes me very forcibly as being a potent causative factor of the complication. With one of the patients the change was gradual and unnoticed other than the fact of a realization that the heart was beating upon the right side instead of left where he had ordinarily been accustomed to feel it. In the other case transposition was sudden, at least in part, because the patient was conscious of the change in position, which occurred during a coughing attack which he had while working and he felt something move in his chest towards the right side. If coughing was responsible in any way for the movement within his chest, then certainly augmentation of volume of the left lung must have been a more important factor at that instant than the adhesions or sclerosis of the right lung which occurred but gradually.

The present measurement of the left chest is greater than one half of the circumference of the whole chest as taken both now and before the transposition, for chest measurements were made

* Presented with two illustrative cases at a meeting of the Boston Clinical Club, July 28, 1905.

* The numerous cases of dextrocardia acquired temporarily as a result of effusion or pneumothorax in the left pleural cavity, but rarely are not this type of displacement.

at regular intervals for a long period two years before any displacements occurred.

From observation of these two cases I should be inclined to say that the emphysematous enlargement of the left lung was not merely a passive filling up of unoccupied thoracic space due to contractile processes on the opposite side, but to an attempt at genuine compensatory hypertrophy which would cause slight pressure upon both the heart and the opposite incapacitated lung.

The physical signs in both these cases, at present, are very nearly the same. The left lung is hypertrophied and there is normal pulmonary resonance over the usual area of cardiac dullness. Fluoroscope shows complete transparency at this point, while on the right there are varying degrees of dullness or flatness over the entire side of the chest, front and back. The cardiac impulse is plainly visible and palpable considerably to the right of the sternum somewhat above the level of the normal position on the left. The boundary of the heart is less easily found by percussion on account of the contiguous compressed and diseased pulmonary tissue in which fibroid changes have doubtlessly occurred. However, the site of the heart can be obtained by means of the fluoroscope which reveals contraction and dilatation of the cardiac shadow.

My cases differ from others which have been reported in that I can give no autopsy findings, but the two cases are unique in that we have records of physical examinations prior to the transposition.

CASE 684B. J. P., male; age, thirty; occupation, coachman; single. Admitted, Sept. 18, 1900. Discharged, Oct. 1, 1901.

Patient gave history of having coughed for one and one-half years; bacilli present; slight hemoptysis in spring, 1894, and spring, 1899.

Examination at entrance showed: Dullness to third rib with slight dullness below; râles also in this region front and back. Respiration very "blowing and hollow" in extreme right apex. *Heart normal.*

Sept. 21, 1900. Dullness to third rib in right apex and to spine of scapula behind. Few crackles increased on inspiration and on cough, more marked in front. Respiration broncho-vesicular in left apex behind. *Heart normal.*

Nov. 23, 1900. Dullness in right upper third in front and upper two thirds behind. Obscure dry râles, not increased after cough, over greater portion of right front, most in top. Respiration rather harsh in right apex. Respiration is decidedly broncho-vesicular with increased expiratory murmur at about one inch below spine of left scapula. (Jan. 31, 1901. Tubercle bacilli numerous.) *Heart normal.*

May 29, 1901. Dullness still persists in upper right front and back to quite a marked degree. Coarse crackling râles, most distinctly heard in top, decreased in number downwards. Local spot of bronchial breathing in left back is less concentrated, and a harsh respiration extends through lower portion of left back. *Heart normal.*

Summary at exit: Oct. 1, 1901. Dullness marked in right front and back. Râles behind much fewer. Very little cough or sputum. Heart slightly rapid. Afternoons (90) during entire stay. Temperature always about normal. Length of stay, twelve months and twelve days. Gained 19 lbs. Discharged. Goes

to work in sanatorium barn. (Moderately advanced phthisis. Very much improved.)

Subsequently: Went to work in sanatorium barn as stableman, feeding O. K. Worked one year when began to feel weak and lose weight; dyspnea quite noticeable. Left the barn and has since been doing light work in the sanatorium. About middle of July, 1904, felt heart beating on right side. Does not remember feeling heart leave its normal position, and has noticed no ill effects from this unusual occurrence.

July, 1905. Marked dyspnea, cough, sputa, etc.; about the same as has existed for past two years, not so severe, however, as to prevent his doing light work. There were numerous physical examinations of the chest made since patient's discharge, sufficient to show that the change in heart position must have occurred between April 1 and July 15, 1904.

CASE 460 C. W. B., male; age, twenty-two; occupation, elevator boy; single. Admitted, Dec. 28, 1899. Discharged, April 17, 1901.

Patient gave history of having coughed for one year. Mother and mother's two sisters died of phthisis. Bacilli present.

Examination at entrance showed: Slight dullness right clavical center; also, slight dullness and sibilant râles in left apex to first rib. Both clavicles prominent. Heart action violent (normal position).

July 23, 1900. Apex beat of heart on (left) mammary line. More dullness at right apex to first rib, and broncho-vesicular respiration. Signs on left gone.

Summary at exit: April 17, 1901. Physical signs same. Cough and sputa still persists. Heart always slightly rapid.

Temperature generally normal. Length of stay fifteen months and twenty days. Gained 93 lbs. Was troubled with cardiac hypertrophy which gave rise to occasional cardiac disturbances with accompanying symptoms. Goes to outside work in Worcester, Mass. Bacilli present. (Moderately advanced phthisis. Very much improved.)

Subsequently: Went to Worcester and worked on the electric cars as conductor for six months. Lost considerable weight and began to feel weak, so returned to Rutland March 19, 1902. Rested for three months, then ran a carriage from the sanatorium to Muschopauge dépôt for four months. Came back to the sanatorium Nov. 1, 1902, and worked in the dining-room nine hours each day. Remained at this work for five months. Exacerbation in May, 1903; rested a while, then went to work, taking care of seven rooms four hours each day. On Aug. 16, 1904, while working, had a severe spell of coughing and felt his heart move from the left side to the right. Became faint, but on lying down for an hour recovered and seemed as well as usual. Continued at work until Dec. 12, 1904, when was taken with chills and faintness and could hardly breathe. In bed three weeks; high temperatures and insomnia. After this, was up and around his room for five weeks. Feb. 7, 1905, left the sanatorium and went to a private boarding-house in Rutland. Began to lose strength with temperature 101° to 103° afternoons during February, March and April. Strength and appetite returned under treatment, and since June 8 has been able to be out-of-doors. Now says he must be careful about his heart; otherwise feels fairly well. Temperature almost always normal since June 8. Physical examinations of heart and lungs were made several times subsequent to the date of discharge, and patient's statement in regard to heart corroborated.

With each of these patients the disease has existed over seven years. At the present time (February, 1906) they can exercise but little, but

the physical signs in the lungs are about the same as nearly a year ago, when marked dullness extended over the entire right lung; one having "cracked pot" percussion note just below the right clavicle. Medium râles were scattered throughout the right and also in the top of the left lung in each case.

Contractile processes are always chronic, but when (compensatory?) emphysematous changes occur in the opposite lung I think the chronicity will probably be even more pronounced.

Clinical Department.

A CASE OF INVERTED UTERUS.*

BY C. H. HARE, M.D., BOSTON.

Gynecologist to Boston Dispensary and to Woman's Charity Club Hospital and to Out-Patients at Carney Hospital and at St. Elizabeth's Hospital.

CALLED upon to operate for an inverted uterus for the first time it was easy to reread, for methods, the paper of Peterson, of Ann Arbor, read before this society March 17, 1903, in which the methods of different operators are described, and the results of these methods, as reported in literature, are brought up to that date, but it was not so easy to select the one correct method, for it seemed a case of many modifications of the two routes, and no one method showing sufficient trial to stamp it as the best beyond dispute. The problem was one in mechanics as to how best to overcome a contracted and unyielding cervix. There must be an increase in the diameter or an incision of this tightening.

Peterson found 15 cases reported operated by the Thomas method or the abdominal celiotomy method, and its modifications by pulling on the tubes and round ligaments and by intra-abdominal incision of the ring. There were 7 failures. Of these 7 failures, 4 had an hysterectomy or amputation done; 1 died and in 2 details were not stated. By all vaginal methods 26 cases were reported, with 3 failures and no deaths. With 88% successful by vagina, and 50% by Thomas method, which later per cent was reduced to 33% when we deduct the cases

where incision was added to his method, it was my choice to operate by the vagina.

It seemed fair argument to recognize the fact that the ring could not always be dilated after abdominal celiotomy and dilating by vagina had not found favor; that by the upper route bruising and tearing of the soft parts was common and sometimes fatal in the most skilled hands; that the majority of cases were weak from hemorrhage, hence worse subjects for shock and sepsis, especially if, as has happened, the inverting pressure used after dilating should puncture a hole from the vagina into the peritoneal cavity; abdominal suspension hardly seemed imperative while vaginal suspension could be done if one was unwilling to risk a retroversion. If a favorable case is at hand, and no one knows whether or not it will be before trial, an incision of the cervical constricting fibres is all sufficient, as has been proven in several cases, and made the operator think the operation for inverted uterus was an easy and simple operation. This was the writer's delusion after his own case, but the error was at once corrected on looking up the literature of this operation. Slightly greater danger of rupture of the uterus in case of subsequent pregnancy after colpohysterotomy had little weight. Statistics argued strongly for a partial extending in case of need to complete anterior or posterior colpohysterotomy. With Piccoli's operation of complete posterior colpohysterotomy or incision from external os to fundus, showing 11 successes and 1 failure, and Spinelli's operation of complete anterior colpohysterotomy showing 6 successes and no failures, the writer decided to do the complete posterior incision in case the slighter methods failed, preferring to take the risks of a retroversion with or without adhesion, rather than the risks of injuring the bladder or ureters by the anterior incision.

Mrs. L.H., age forty, married twenty years; seven children, two miscarriages. She was first seen by me fourteen days after her last child had been born. The previous child was four years old. Menstruation had always been every twenty-eight days, flowing six days and using about twelve napkins. No dysmenorrhea. She had never had any pelvic trouble. She was attended by a man of very large obstetrical training, to whom I am indebted for the history. She had some labor pains for about forty-eight hours which were moderately hard the last twelve hours. She delivered herself and the placenta followed at once, without trouble. There was profuse hemorrhage. Convalescence was normal and he sat up on the day of my first visit. The lochia was the same as after her other childbirths. There had been no pain. General weakness was her only complaint to me. Examination showed an old tear of the perineum and a mass at the vagina, but no fundus could be felt by the finger in the abdomen. Moderate flowing followed for a week. Refraining to wait for operation, I decided to bed for general building up. She was discharged Feb. 24, 1905, or twenty days after the birth. The urine was then acid, specific gravity 1012, 1013, 1014, 1015, men, but sugar was present unless there was an error in the test, for it was never found in the following days' later test. The hemoglobin was 50% and the openings of the Fallopian tubes were not seen. It

* Read before the Obstetrical Society of Boston, Oct. 24, 1905.

seemed so easy to think that taxis would replace, that it was tried without the slightest evidence of success. This dilated the uninverted portion of the cervix, but in no way touched the tight collar or constricting inner ring. The posterior lip of the cervix was then incised and the cut continued upwards for about one and a half inches, when a "give" was felt which made me try to reinvert and to my surprise the fundus went back with ease. Another surprise was to find that no opening had been made into the peritoneal cavity. The incision was closed with catgut and the uterus then was found in good position.

Looking back for an explanation of the ease of this operation the writer believes that taxis produced the great and essential, though unplanned for condition, which made possible the easy replacement. The squeezing incident to taxis made a large fundus small and squeezed out fluids which converted a solid, firm fundus into one of a pliable, leathery consistency. The patient made a good convalescence without temperature or pulse, but because of poor general condition and many vigorous children at home, she did not leave the hospital until the seventeenth day after operation, when the hemoglobin was 70%; the uterus in perfect position and with perfect mobility.

There is little argument in one case, but from theory and statistics the writer believes that operation for inversion of the uterus should be considered easy until proven difficult. If conditions are favorable a short incision by vagina permits replacement, but this failing, we only have to extend the same incision, after the loss of a few minutes, to a point where reinversion seems assured.

The patient was seen to-day (Oct. 24). She is an overworked woman in poor general condition, having lost weight from 172 down to 147 lbs. in two years. The first three menstruations after operation were profuse, but scanty since, flowing five days with one napkin daily. No dysmenorrhea; no leucorrhoea. The uterus is in good position and freely movable. The cervix shows no evidence of operation, but looks like the ordinary, slightly torn cervix. She has no pelvic complaint and, in fact, has not seen any doctor since she left the hospital until she called her doctor for pleurisy two weeks ago.

A CASE OF EXTRA-UTERINE PREGNANCY.*

BY JOHN B. SWIFT, M.D., BOSTON.

THE interest, centering in the diagnosis of this case, seems to make it worthy of reporting.

The patient is a married woman, thirty-two years old. She has had four children; no miscarriages. She has always been well. I have attended her in her last three confinements. The labors have been easy, and the convalescence always normal. After her first confinement she had a retroversion of the uterus which was corrected by Alexander's operation, and the uterus has remained in good position ever since.

Her catamenial history is normal, the intermenstrual period being twenty-three to twenty-five days, and the flow lasting seldom more than two days. The youngest child is twenty-six months old.

Regular menstruation took place on Aug. 27, 1905, but, four days after the flow had ceased, there was a dark brown gritty discharge for several days. On Sept. 19, being the time for her catamenia, she was seized, while at breakfast, with a sudden sharp, very severe pain in the lower abdomen, beginning on the

right side. She felt faint, but did not lose consciousness. The pain was continuous, the abdomen became swollen and very tender, and there was a slight flow from the vagina, "just a stain."

The physician, who was called in, controlled the pain by a subcutaneous injection of morphia. Among other things a tubal pregnancy was suggested as the cause of the attack, and she was kept under careful observation. He has assured me that, at no time while she was under his care, was there any shock, aside from the faintness, or evidence of hemorrhage. The temperature was always normal, and the pulse about 80. She remained in bed about a week, during which time there were two slight attacks of pain, one on Sept. 21, the other on Sept. 23, neither of which required morphia.

She came to my office on Oct. 3 because she did not feel well, but could give no definite symptoms. She did not think pregnancy could be possible.

On palpation the abdomen was soft and yielding. There was some tenderness on deep pressure on the left side. No flatness or dullness on percussion.

By vagina the uterus was of its usual size and position, and I detected nothing wrong anywhere in the pelvis.

I advised her to remain in bed for another week and then to come to see me again, thinking, that, if she had had a tubal pregnancy which had ruptured, absorption would go on, but, if the sac was still growing, something might be felt later. She came at the appointed time having had no further trouble, but saying she felt much better.

On vaginal examination *something* could be felt to the left and behind the uterus, but I could make out nothing definite.

She was advised to come in to one of the private hospitals for an examination under ether, and operation, if any thing was found to warrant it. She objected to the hospital, saying her house in town was all ready for her to move into, so it was decided that she was to come home in two days. The night before she was to move they telephoned that she had a severe pain in her stomach, not like the former pain. I talked with the physician in attendance, who said this attack was nothing like extra-uterine, but rather like acute indigestion. It was suggested that a nurse be sent to them to assist in moving her to town. The next morning the nurse telephoned me that she did not think the patient should be moved that day, and asked that I go to see her. I found her rather nervous over the delay of moving. The nurse told me the attack of the preceding evening seemed to be due to indigestion, as the patient was relieved after vomiting undigested food. There had been no more abdominal symptoms. She came to town Friday, Oct. 13, and when I saw her, the next morning, she greeted me with the remark that she could not be pregnant as her regular menstruation had come on, and she felt well in every way. The nurse had found a small shred on one of the napkins which Dr. Whitney reported to be blood clot. On Oct. 16 she passed a clot resembling somewhat a cast of the uterus. Dr. Whitney reported on this: "Masses of clotted blood, among which were mingled large, single, nucleated cells similar in every way to those of a decidua. I could not find, however, any villi, or other evidence of intra-uterine pregnancy."

The original idea of an ether examination, with operation if found necessary, was decided on. On Oct. 19, under ether, there was found to be a mass, as large as my fist, behind and to the left of the uterus. The uterus was curetted, and then the abdomen was opened in the median line. On cutting the peritoneum

* Read before the Obstetrical Society of Boston, Oct. 24, 1905.

dark fluid blood welled up through the incision. The omentum was slightly adherent in places to the abdominal peritoneum. The abdominal cavity was full of fluid blood and clots, among which the fetus was found. The fetal sac was in the fimbriated extremity of the left tube, and the uterine operation was completed.

The specimen was given to Dr. Whitney, who reported:

"The specimen consisted of the end of a Fallopian tube. In this was a hemorrhagic mass measuring 6 cm. in diameter, the inner surface of which was covered with a smooth membrane. Microscopic examination of the wall showed masses of blood and fibrin intermingled with which were small branching villi similar to those of the chorion. With this specimen was a small embryo, well formed and but little macerated, measuring 2.7 cm.

"Diagnosis: Ectopic (tubal) pregnancy with rupture at about the eighth week."

The especial points of interest seem to be the question of diagnosis, and the time when the rupture took place.

With such a history as was given, when first seen by me, was there sufficient evidence to make a diagnosis of extra-uterine pregnancy? Was there sufficient evidence of any pelvic trouble demanding operation? Had rupture taken place at the time of the first attack of pain, would there not have been evidence of it which could not be missed by bimanual examination? It seems impossible that the condition found at the operation could have been overlooked by any one, least of all by one accustomed to making vaginal examinations. If, as Dr. Whitney suggests, rupture occurred Oct. 14, that is, on the day she thought she was menstruating, why was there not some evidence of it manifested by the presence of pain, and symptoms of hemorrhage?

AN INDIRECT ADVANTAGE OF THE ROUTINE APPLICATION OF CLINICAL PATHOLOGY TO DIAGNOSIS.

By LOUIS PATTERSON BISHOP, A.M., NEW YORK,
Physician to Lincoln Hospital.

An eminent Philadelphia physician some years ago, spoke of the therapeutic value of the complete physical examination, and his remark struck men of experience as containing a great deal of truth.

There is no question about the diagnostic value of a complete physical examination followed by the findings of clinical pathology. There is one advantage in the routine application of clinical pathology that it does not seem unfair to recognize, and that is the fact that it gives the consultant time for reflection, and gives him an excuse for postponing a definite opinion when a hasty conclusion may be disastrous. By organization we have brought about that a blood count can be obtained promptly without great cost, but even so two or three hours must elapse. The consulting physician occupies a position of great difficulty. He sees the patient only once and under more or less artificial conditions. His history is sometimes so confused by defects of observation, memory and complicating conditions

that often enough the opinion must be based chiefly upon results of direct examination.

A case where appendicitis is suspected must often be determined solely upon findings of abdominal palpation. Take a case like the following which is drawn from recent experience: A man was seen late at night, who gave the following history: He had been drinking to excess for a long time and much more for the past few days. Two days previously he began to suffer from nausea and vomiting; he was very much constipated and had a slight elevation of temperature. For the last twelve hours before he was seen attempts at feeding had been promptly followed by vomiting. He had not been able to sleep and was very nervous, indeed, apparently upon the verge of an attack of delirium tremens. His temperature was 101°. The abdominal palpation showed no marked rigidity, the belly was tender all over, there was no distention. Appendicitis was thought of, but the most careful elicited no history of chill, no history of marked tenderness on the right side of the abdomen at any time, and no history of a previous attack. Our opinion from the findings was that the abdominal symptoms could be fully accounted for as a result of the continued vomiting that had gone before. We did not see the patient again, but are told that on the following day there was marked tenderness on the right side a mass was detected in the region of the appendix.

Now, a case like this naturally causes chagrin on the part of the person who was led to give an opinion though it was such as he would, in all probability, repeat under similar circumstances. Still, if one made it a personal rule never to exclude intra-abdominal suppuration without a blood count, such a hasty opinion would not be forthcoming; and, in addition to the light thrown upon the case by clinical pathology, there would be the advantage of the elapse of a small amount of time, the developments of which could be included in the final conclusions. The more one sees of the graver forms of disease and watches their course under all circumstances, the more careful one becomes as to the formation of a so-called snap diagnosis.

Every active practitioner should have the service of a recent graduate well trained in clinical pathology. Or, as has been done in New York, a group of busy men might organize a co-operative laboratory to employ a group of young men during their pre-practice period.

Reports of Societies.

THE OBSTETRICAL SOCIETY OF BOSTON.

The three hundred and sixty-seventh meeting of the Society was held Oct. 24, 1905. The Howard Robinson chair, J. C. Hubbard, M.D., presided.

Dr. HARD reported:

A CASE OF INVERSION OF THE UTERUS.

DR. STEVENS. In one case of this condition I employed Emmet's method. I forced the fundus back

Nov. 1, 1905

of the cervix and then sutured the cervix over it. During the following night the fundus went back entirely. Six months later I saw an anemic woman who had been delivered one year previous. An inverted uterus was found. The same treatment was used with the same result. Within twelve hours the fundus was replaced spontaneously.

DR. WASHBURN: I have seen but one of these cases. I saw her a week after the inversion took place. She had had extreme hemorrhage. Patient was in poor condition. Moderate manipulation was tried and failed. A firm packing was put into the vagina to control any bleeding. The second packing had so far reduced the uterus that it was easily replaced. The packing itself had exerted sufficient pressure to render this easy. The placenta had been adherent and the cord had been pulled on by the attending physician. The convalescence was uneventful.

DR. KAHN: I have never seen a case of inverted uterus following delivery. I have seen one case where fibroids in the vagina were connected with an inverted uterus.

DR. MARION: I remember Dr. Stevens' case. I have reported before this society two cases of inverted uterus immediately following delivery.

DR. HILDRETH: I can emphasize the difficulty of Dr. Stevens' case. I have had one case of recent inversion. The early labor was very severe and the last part very rapid. The child, placenta and uterus all came out together with one pain. The uterus was immediately replaced. There was much shock, but the recovery was good.

DR. DAVENPORT: One more suggestion. If effective pressure can be brought on the constricting ring before fibrous changes occur it takes advantage of the fact that the muscles of the uterus relax fairly easily under constant effective pressure.

DR. REYNOLDS: How would Dr. Stevens treat such a case seen to-morrow?

DR. STEVENS: Operative interference now has more certainty of success than formerly. I think the operation described by Dr. Hare, division of the ring, would be preferable to the method used by me.

DR. SWIFT then reported

A CASE OF EXTRA-UTERINE PREGNANCY.

DR. DAVENPORT: Under ether could free blood be made out in the abdomen?

DR. SWIFT: I should say not.

DR. STEVENS: Within a year I saw a woman who had been flowing for three weeks. Three weeks previous she had had an attack of abdominal pain, accompanied with faintness. She was able a few days later to resume her work. She had not lived with her husband for sixteen years, but on close questioning admitted that she had accommodated a friend. During my examination she had much pain and grew faint. She was removed immediately to a hospital and operated upon. A ruptured tubal pregnancy was found, the rupture having occurred during the examination in my office.

DR. HARE: I have had a case similar to that of Dr. Stevens.

DR. J. G. BLAKE: In my experience an extra-uterine pregnancy is more likely to occur when there has been a long period between children.

DR. SWIFT: I think such an interval is often given in the histories of such cases. When the sac is in the fimbriated end of the tube it may more easily escape the examining fingers than when near the uterus.

DR. REYNOLDS: I remember a case of this sort. On examination all that could be made out was a tender

spot. Under ether what seemed like an enlarged ovary was felt. Operation was insisted upon. An extra-uterine pregnancy was found the size of a large hen's egg at the extreme outer end of the tube which had ruptured through all its coverings except the peritoneum. The patient has had several children since.

DR. HILDRETH showed some photographs of an erectile tissue growth on the areola of the breast. It was too near the nipple to allow the baby to nurse. Milk came from an opening in it.

DR. J. G. BLAKE: A careful dissection of the mass after lactation is over might be of benefit.

DR. REYNOLDS: If milk ducts are cut there will surely be a breast abscess with the next confinement.

DR. YOUNG: I recently reported in the BOSTON MEDICAL AND SURGICAL JOURNAL a case with two nipples on one breast. An extra nipple is connected either with one lobe of the breast or with practically a second breast.

Voted to allow the secretary to place the records of the Society in the Boston Medical Library.

Recent Literature.

Ready Reference Handbook of Diseases of the Skin. Fifth edition. By GEORGE THOMAS JACKSON, M.D. With 91 illustrations and 3 plates. New York and Philadelphia: Lea Brothers & Co. 1905.

This excellent epitome of skin diseases has now reached its fifth edition. In the present edition many new sections have been added on forms of cutaneous diseases that have received special attention of late. The book is compiled with the well-known care that its author always shows in his medical publications, and is to be heartily recommended to those who find the larger textbooks of too great bulk for convenient handling. The plates are all good of their kind.

Gumption: The Progressions of Newson New. By NATHANIEL C. FOWLER, JR. Boston: Small, Maynard & Co. 1905.

This is a sociological satire in the form of a novel. The hero's father and one of his brothers were doctors. The father practised at and around Yarmouth on Cape Cod. He was "a genuine, hempsewed, corn-fed country physician, of the gray-haired class of our oldest school. He neither wore kid gloves nor practised in them. His patients either had to get well or die, with no loitering on the way. He felt the pulse with one hand and poured castor oil with the other. Put your trust in castor was his creed." He subsequently went to Boston and settled in Roxbury where he continued to do well.

The brother went back to Cape Cod, preferring to be a big Cape Codder rather than a little Bostonian. He "treats by modern medicine, mental, sometimes rather a crude, more or less, science and systematic sympathy."

Both father and brother exploit the art rather than the science of medicine. There is not much reverence for the "is" in these pages, but they exhibit some shrewd observation of mankind and of human nature.

The Management of a Nerve Patient. By ALFRED T. SCHOFIELD, M.D. 12mo, pp. xii, 267. Philadelphia: P. Blakiston's Son & Co. 1906.

In the volume before us, the writer returns to the text from which he has been preaching for several years, — the importance of mental treatment of disease, of a study of the personality of the patient and of the influence of the personality of the physician. The details of the treatment of the neurasthenic are given with great prolixity, even to the minutest particulars of the reception of the patient in the physician's office. The work contains nothing new, is more than prolix and dwells upon the commonplaces that should be familiar to every physician, yet it is a lamentable fact that there are a very large number of physicians who neglect or are ignorant of these banal methods of professional conduct, and who would be decidedly benefited by taking counsel from this and the other volumes of the author.

Laboratory Guide in Experimental Pharmacology. By CHARLES W. EDMUNDS, A.B., M.D., Instructor in Pharmacology in the University of Michigan, and ARTHUR R. CUSHNEY, A.M., M.D., Professor of Chemistry in University College, London, and late Professor of Materia Medica and Therapeutics in the University of Michigan. Ann Arbor, Mich.: George Wahr, 1905.

This work consists of directions for the course in pharmacology given to the students of the University of Michigan. There are detailed instructions for the use of anesthetics to animals, the application of certain drugs or their active principles to animals, to show their physiological action; there are full directions for making extracts, fluid extracts, tinctures, emulsions and pills, and brief statements regarding the chemistry of some of the more important drugs. The plan of instruction is systematic and thorough, and we are convinced that a student who has conducted the experiments and followed the directions given will have a useful knowledge of pharmacology. The book should receive recognition by teachers of this subject in other medical schools.

Compend of the Diseases of the Skin. By JAY F. SCHAMBERG, A.B., M.D. Fourth edition, revised and enlarged, with 108 illustrations. Philadelphia: P. Blakiston's Son & Co.

In the fourth edition of this compend of skin diseases, the author has made sundry additions and revisions, and has added extra chapters on actino-therapy and radio-therapy.

JOHN T. BOWEN

A Manual of Physical Diagnosis, including Diseases of the Thoracic and Abdominal Organs For Students and Physicians. By EDMUND L. FEYRE, M.D., Professor of Clinical Medicine and Therapeutics in the University and Bellevue Hospital Medical College, Attending Physician to Bellevue Hospital and to St. Luke's Hospital, New York. Second edition, thor-

oughly revised and much enlarged. pp. 479. Philadelphia and New York: Lea Brothers & Co. 1905.

In this new edition the author has brought his subject completely up to date. Some sections have been entirely rewritten, and many new illustrations have been introduced. The text and cuts are clear, and, on the whole, give to the student and physician a very adequate picture of normal and pathologic conditions and of their accompanying physical signs.

Saunders' Medical Hand Atlases. Atlas and Epitome of Diseases of the Skin. By DR. FRANZ MRAECK, Professor of Dermatology in the University of Vienna. Authorized translation from the German. Second edition, revised and enlarged. Edited by H. W. STELWAGON, M.D., Ph.D. With 77 colored plates and 50 halftone illustrations. Philadelphia and London: W. B. Saunders & Co.

In this second edition of Mraeck's Hand Atlas the author has, as he states in his preface, increased the number of colored plates and also the halftone cuts, so as to make it properly reflect the dermatology of to-day. His text has also been considerably revised. As was the case with the last edition, many of the illustrations are extremely good. If any criticism be ventured, it would be that in certain of the plates one is impressed by a rather too high scheme of coloring. The book is issued in a very convenient form, and will prove as useful for the needs of the general practitioner as many more elaborate and expensive atlases.

Treatise on Diseases of the Skin for the Use of Advanced Students and Practitioners. By HENRY W. STELWAGON, M.D., Ph.D. Fourth edition; thoroughly revised, with 258 illustrations in the text and 32 full page lithographic and halftone plates. Philadelphia and London: W. B. Saunders & Co. 1905.

Dr. Stelwagon's textbook of diseases of the skin has reached its fourth edition in an almost incredibly short space of time. The present edition has been enlarged by an admirable description of the use of the Röntgen ray, high frequency current and concentrated light rays in diseases of the skin. There are a number of new cuts inserted in the text, most of them examples of the diseases most frequently encountered others representing some of the rarer diseases. It is matter for congratulation that the colored plates taken from the Mraeck "Hand Atlas" which appeared in the earlier editions, have been taken out and replaced by colored illustrations of the author's own cases. The Mraeck colored plates, as was pointed out in a notice of the earlier editions, detracted from the appearance of the book. Dr. Stelwagon's own colored plates are much better, even here however there seems a suggestion of over-coloring. The book is as has been said before, an admirable one, perhaps better suited for general use as a text-book than any now existing.

THE BOSTON Medical and Surgical Journal.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

THE ANNUAL REPORT OF HARVARD UNIVERSITY, 1904-05.

As usual this report discusses a variety of important university and academic questions in a trenchant and illuminating manner. The president of Harvard knows what he thinks on most if not all subjects, can state clearly and forcibly what he knows, and certainly dares maintain.

A discussion of the three years' course for the degree of A.B. is thus summed up:

"This table, therefore, demonstrates, first, that by utilizing all the existing facilities young men of good parts may get the Harvard A.B. in three years without making any unreasonable or disadvantageous exertions, and secondly, that the presence in the courses of instruction of young men who propose to get the degree in three years is not likely to impair in any way the quality of the courses, since the three years' men are, as a rule, better scholars than the four years' men. It is apparent that any young man who has made good use of the instruction offered in a good secondary school, and is then willing to use for purposes of study one half of the college vacation time, can procure the Harvard A.B. with distinction in three years, without any over-exertion, and will also have had a better training for efficiency in subsequent work at his professional school or in business than if he had taken four years to get the A.B. degree."

An interesting table is given intended to exhibit the various measures in which nine universities named recruit their medical schools and law schools from persons who have already received a preliminary degree in arts or science. Harvard is the only one of these institutions, Mr. Eliot

says, "which requires a preliminary degree for admission to its professional schools; but in several other institutions, notably at Chicago and Columbia, a considerable proportion of holders of a preliminary degree is to be found in the schools of Law and Medicine. State universities are as a rule deficient in this respect. An important aspect of this matter is the fact that the strongest support any university can give to the preliminary degrees in arts and science — its own, or those of other institutions — is the requirement of such a degree for admission to its professional schools. There would be no question about the future maintenance of that peculiarly American educational institution called a college, if the universities of the country would require an A.B. or an S.B. for admission to their professional schools."

| 1904-05. UNIVERSITIES. | MEDICAL SCHOOLS. | | | LAW SCHOOLS. | | |
|---------------------------|-----------------------------|--|------|-----------------------------|--|------|
| | No. of Male Students. | Holders of a Preliminary Degree. | | No. of Male Students. | Holders of a Preliminary Degree. | |
| Chicago | 238 | 106 | 44.5 | 157 | 94 | 59.9 |
| Columbia | 562 | 250 | 44.5 | 343 | 282 | 82.2 |
| Cornell | 355 | 54 | 15.2 | 224 | 23 | 10.3 |
| Harvard | 307 | 267 | 87.0 | 758 | 755 | 99.6 |
| Illinois | 601 | 92 | 15.3 | 129 | 9 | 7.0 |
| Michigan | 342 | 79 | 23.1 | 867 | 109 | 12.6 |
| Northwestern | 591 | 114 | 19.3 | 225 | 70 | 31.1 |
| Pennsylvania | 546 | 171 | 31.3 | 301 | 105 | 34.9 |
| Yale | 139 | 19 | 13.7 | 234 | 82 | 35.0 |

Mr. Eliot again addresses himself to the game of football and belabors it in good set fashion. Last year four pages of the report were devoted to it; the game and the conditions under which it is played were termed "hateful." This year a little more than a page suffices for the subject, but it is a terse and vigorous page. The arraignment is on much the same grounds as before, but more specific and, if possible, more emphatic. Beginning with the statement that the American game of football as now played is wholly unfit for colleges and schools Mr. Eliot enters eight specific indictments against it, which may be briefly summarized as follows:

"(1) It causes an unreasonable number of serious injuries and deaths; not one in five of the men that play football several seasons escape without injury properly called serious, and of the twenty to thirty picked players who play hard throughout a season hardly a man escapes serious injury. The public has been kept ignorant concerning the number and gravity of these injuries, the prevailing practice among coaches and players having been to conceal or make light of the injuries sustained.

"(2) Violations of the rules of the game by coaches, trainers and players are highly profitable, and are constantly perpetrated by all parties.

"(3) In any hard-fought game many of the actions of the players are invisible to the spectators, and even to the referee and umpire; hence much profitable foul play escapes notice.

"(4) The game offers many opportunities for several players to combine in violently attacking one player.

"(5) There is no such thing as generosity between combatants, any more than there is in war.

"(6) Acts of brutality are constantly committed, partly as results of the passions naturally aroused in fighting, but often on well-grounded calculations of profit towards victory.

"(7) As a spectacle, for persons who know what the game really is, football is more brutalizing than prize-fighting, cock-fighting, or bull-fighting. Regarded as a combat between highly trained men, the prize ring has great advantages over the football field; for the rules of the prize ring are more humane than those of football, and they can be, and often are, strictly enforced. There are no secret abominations as in football. Yet prize-fighting is illegal.

"(8) The game sets up a wrong kind of hero — the man who uses his strength brutally, with a reckless disregard both of the injuries he may suffer and of the injuries he may inflict on others. That is not the best kind of courage or the best kind of hero.

"All these evils of football have now descended from the colleges into the secondary schools, where they are working great moral mischief. It is clearly the duty of the colleges, which have permitted these monstrous evils to grow up and become intense, to purge themselves of such immoralities, and to do what they can to help the secondary schools to purge themselves also. Intercollegiate and interscholastic football ought to be prohibited until a reasonable game has been formulated and thoroughly exemplified in the practice of individual institutions. It is childish to suppose that the athletic authorities which have permitted football to become a brutal, cheating, demoralizing game can be trusted to reform it."

The Medical Visitor reported ten deaths among students in the Cambridge departments of the University, which means among about 4,400 individuals; of which eight were by disease and two by accident. The use of the Stillman Infirmary, and especially of the wards, is steadily increasing. The new system of charging each student in the Cambridge departments four dollars a year as an infirmary fee, this entitling him to a fortnight's treatment at the infirmary, encourages such a tendency. The finances of the infirmary are now on a satisfactory basis.

On turning to the Medical School we learn that there was, as in the period covered by the preceding report, a considerable deficit and there is

likely to be a deficit again next year. The current year will probably be the last to be spent in the present building. It is not possible to determine now how much of the great gifts made to the Medical School undertaking as a whole in 1901-03 will remain as an endowment for maintenance. The president remarks that the undertaking was conceived on a large scale, and with more regard to future needs and opportunities than is usual in university enterprises.

A free elective system with a considerable range of options has been adopted and has gone into force during the current year. In regard to this change the dean tells us that the advocates favored it for two reasons: some thought it would be advisable to allow students who had made up their minds to go into some special, rather than general, practice, to prepare themselves in the branches to which they intended to devote their lives; others thought that students who preferred laboratory to clinical courses should be allowed to select work along those lines. Those who were not in favor of the change opposed it from the standpoint that four years was not too long a period to be devoted to a required course, and that a student should not be allowed to make any departure from the regular curriculum until he had received his degree.

The choice of studies actually made by the students is, therefore, especially interesting. A careful examination of a table compiled from this point of view shows that, with an unlimited choice of subjects for the coming year, the students have practically chosen to continue the same work which was heretofore required. They have not elected specialties and have shown no desire to select laboratory in preference to clinical work. In other words, they have shown that they prefer to continue their preparation for the general practice of their profession.

There has been a very decided increase in the number of summer and graduate courses taken, and in the number of students availing themselves of the instruction offered in these two departments of the Medical School during the past year. In connection with the summer work attention is called to the fact that the students in attendance came from twenty-nine different states in the Union, the District of Columbia, Australia, China and Canada.

If properly fostered it would seem as if, with the new arrangements, a very considerable immediate and steady expansion in the attendance upon these graduate and summer courses might be confidently anticipated.

The activity in medical research has been fully maintained in all of the laboratories by both teachers and students as is shown by the long list of publications reported.

The Dental School is extending and enlarging its work in several directions and having purchased a lot of land adjoining the land of the Medical School is now at work endeavoring to raise money to provide for an endowment and to pay the cost of a new building for which plans have been prepared.

THE PUBLIC AND THE MEDICAL PROFESSION.

It is at times well to know what others think of us. The medical profession has always had its share of criticism, both friendly and otherwise, and we are glad to make note of a still further admonition from ex-President Grover Cleveland. At the recent centennial exercises of the State Medical Society of New York, held in Albany, Mr. Cleveland gave the principal address. The burden of his remarks was that physicians should take patients more into their confidence. He divided humanity into two unequal sections, one composed of the doctors, and the other including the millions of their actual or prospective patients. He appeared for the latter section and maintained that the tendency of the other had been to curtail freedom of thought and considerate hearing, to which the majority, he held, was entitled. He made a plea for less mystery and aloofness on the part of physicians; he cast a slur, we think with some justice, upon the still prevalent pigeon Latin and ponderous terms in use for diseases which might be designated more simply. We do not, however, follow him when he says that recent discoveries have led to additional mystery and additional inclination on the part of the doctors to "stately superiority." Carrying the argument further and recognizing the advance which has been made in medical knowledge, and the self-sacrificing work of many practitioners, he felt that the laity also had increased in knowledge and should be treated accordingly. The patient should be taken into closer comradeship; he should be allowed to know many things about his illness, which it is claimed is denied him at present, and there should in general be greater publicity between physician and patient. The growth of the nostrum evil he likewise attributes to the failure of physicians to enter into close personal relationship with their patients. Mystery should be avoided and remedies and treatment more frankly discussed.

Coming from such a source the foregoing remarks are both instructive and salutary. To much that Mr. Cleveland says we unhesitatingly agree. We are, however, inclined to think that were he standing on the other side he would appreciate some of the difficulties against which the medical profession has to contend and which are too frequently misinterpreted by the laity. The relation between physician and patient has been a gradual evolution and is unquestionably quite different now from what it was thirty or forty years ago. The mystery surrounding disease and its cure is being laid aside just as rapidly as the education of the public permits. No better example of this could be offered than the recent publicity given to the whole subject of tuberculosis. It would, however, not conduce to the advantage of either patient or physician if in the present state of progress diseases were discussed publicly, the understanding of which depends upon special training. Furthermore, the relation of the physician to the patient is so purely a personal matter that generalizations should be made with much caution. It is not difficult to understand that Mr. Cleveland's relation, for example, to his physician may, and, in fact, must, be very different from that of some other person of a wholly different grade of intelligence. Physicians of any experience quickly learn that no two patients can be treated exactly alike and that confidential relations must vary widely with the individual. In general, however, Mr. Cleveland has well expressed a situation which is of equal interest to physician and layman. He is right in his opinion that a greater degree of sympathetic confidence should exist between the two classes in the community; he is wrong, we think, in supposing that this is not coming to be the fact, and is equally in error in supposing that with the advance of medical knowledge a greater aloofness is developing between physician and patient.

MEDICAL NOTES.

ENCOURAGEMENT ONE THIRD THE BUSINESS OF THE PHYSICIAN. — Dr. Richard C. Cabot of Boston, in a suggestive article in *Charities*, in which he described the impotency of the physician to affect through his technical skill or knowledge much that he would like to do, has this suggestive opinion to record: "Encouragement is one third the business of the physician, but if it is to be permanent and not a mental cocktail, we must give the patient good reason for being encouraged, which usually means religion or its equivalent."

He then adds the significant admission: "It is the disregard of these facts that has sent so many patients away from physicians and into the hands of Christian Scientists and mental healers." — *The Congregationalist and Christian World*.

ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. — The Rockefeller Institute for Medical Research purposes to award for the year 1906-07 a limited number of scholarships and fellowships for work to be carried on in the laboratories of the Institute in New York City, under the following conditions: The scholarships and fellowships will be granted to assist investigations in experimental pathology, bacteriology, medical zoology, physiology and pharmacology, and physiological and pathological chemistry. They are open to men and women who are properly qualified to undertake research work in any of the above mentioned subjects and are granted for one year. The value of these scholarships and fellowships ranges from six hundred to one thousand dollars. It is expected that holders of the scholarships and fellowships will devote their entire time to research. Applications accompanied by proper credentials should be in the hands of the secretary of the Rockefeller Institute, L. Emmet Holt, M.D., 14 West 55th Street, New York City, not later than April 1, 1906. The announcement of the appointments is made about May 15. The term of service begins preferably on Oct. 1, but, by special arrangement, may be begun at another time.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Feb. 7, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 46, scarlatina 29, typhoid fever 5, measles 202, tuberculosis 50, smallpox 0.

The death-rate of the reported deaths for the week ending Feb. 7, 1906, was 21.38.

BOSTON MORTALITY STATISTICS. The total number of deaths reported to the Board of Health for the week ending Saturday, Feb. 3, 1906, was 233, against 213 the corresponding week of last year, showing an increase of 20 deaths and making the death-rate for the week 20.42. Of this number 125 were males and 108 were females; 228 were white and 5 colored; 147 were born in the United States, 83 in foreign countries and 3 unknown; 47 were of American parentage, 156 of foreign parentage and 30 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria,

38 cases and 4 death; scarlatina, 27 cases and 1 death; typhoid fever, 8 cases and 2 deaths; measles, 203 cases and 2 deaths; tuberculosis, 49 cases and 30 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 38, whooping cough 2, heart disease 30, bronchitis 5 and marasmus 4. There were 8 deaths from violent causes. The number of children who died under one year was 36; the number under five years, 59. The number of persons who died over sixty years of age was 62. The deaths in public institutions were 82.

There were 2 deaths and no cases reported from cerebrospinal meningitis during the week.

DR. McLEOD NO LONGER A MEMBER OF THE MASSACHUSETTS MEDICAL SOCIETY. Dr. Percy D. McLeod, recently brought into prominence through his connection with the so-called "suit case mystery," has been found by the Trial Board of the Massachusetts Medical Society to be guilty of conduct unbecoming a member of the society. The penalty for this offence is expulsion from the society.

FEES OF MEDICAL EXAMINERS. — A committee consisting of Drs. T. W. Twitchell, E. H. Thompson and F. E. Jones, appointed at the annual meeting of the Massachusetts Medico-Legal Society to investigate the fees paid to medical examiners in cases of homicide in the various courts of this state, reports as follows:

That letters requesting information in this matter were sent to the presiding justice of each municipal, police and district court, and to each district attorney in this commonwealth, in all numbering seventy-six; that fifty-five replies have been received; that in the eight municipal courts no fees are paid to medical examiners, who receive an annual salary in these districts, that replies from eight police courts show that four have had no homicide in their jurisdiction. Two allow fifty cents per day and mileage. In one the medical examiner's bill for service in court is sent to the county. In one five dollars is allowed for each day's attendance either at the inquest or trial, that replies from thirty-two district courts show that fifteen allow the ordinary witness fee, fifty cents per day and mileage. Five report no cases in their jurisdiction. Two report that they allow an ordinary witness fee and a special fee commensurate with time taken of an expert testimony given.

One reports allowing two dollars for attendance per day at the inquest and one and one-half to three dollars for attendance per day at the trial.

One reports allowing two dollars for attendance per day for any service in his court. One reports allowing three dollars for attendance per day for any service in his court. Three report allowing five dollars for attendance per day for any service in their court. One reports allowing three or five dollars for attendance per day at the inquest and ten dollars per day for trial. Two report allowing ten dollars for attendance per day for either inquest or trial. One reports allowing any reasonable fee for attendance in his court.

Replies from seven district attorneys show that two have no uniform fee for attendance per day on the grand jury or the criminal court; one allows ten dollars fee for attendance per day on the grand jury and twenty-five dollars at the criminal court; one allows fifteen dollars for attendance per day on the grand jury and twenty-five dollars at the criminal court; one allows a discretionary fee, about twenty-five dollars; one allows ten dollars for attendance per day on either court; one allows fifteen dollars for the first day, then ten dollars and in cases of consultation twenty-five dollars.

The committee also reports that in their opinion, the equalizing of these rates can be best obtained if each medical examiner in such districts where the fee allowed is unreasonably low would personally show the justices and district attorneys of these districts the report of the committee, and intimate that the practice of allowing a special fee in such cases is lawful and common and proper.

NEW YORK.

BEQUESTS TO HOSPITALS. — By the will of the late Mrs. Sarah McLean Abernethy the sum of \$5,000 is left to the Woman's Hospital, to endow a bed, and by the will of Jacob Hoffman, \$500 each to the German Hospital and Dispensary and St. Francis Hospital.

UNITED CHEMISTS COMPANY. — "The United Chemists Company" has been incorporated in New Jersey with a capital of \$10,000,000, and its object is stated to be to do in the retail drug trade in New York City what the United Cigar Stores Company has done in the tobacco trade. The company's charter permits it to operate pharmacies only in cities with a population of one million or more, and its territory is, therefore, restricted to New York, Chicago and Philadelphia.

BOARD OF ESTIMATE AND APPORTIONMENT. — At a meeting of the Board of Estimate and Apportionment held Feb. 2 the City Health Depart-

ment received an appropriation of \$10,000 for the continuance of its medical commission for the investigation of acute respiratory diseases, and \$5,000 for its cerebrospinal meningitis commission. In addition, \$35,000 was appropriated for expenses in connection with the prevention and treatment of diphtheria, \$15,000 for the maintenance of the tuberculosis clinic in Manhattan, and \$10,000 to provide additional nursing facilities.

MAGIC-MECHANICO-PHYSIOLOGICAL BOOTS. — The New York County Medical Society, through its counsel, is still vigorously carrying on its warfare against quacks. On Jan. 31 "Professor" Matthew H. Hilgert and his chief assistant, Albert Whitehouse, an osteopath, were arraigned before Magistrate Pool in the Jefferson Market Police Court on charges of practising medicine without a license, and held in \$500 bail each. These men have been engaged in the flourishing business of selling "magic-mechanico-physiological boots," advertised to cure locomotor ataxia, hip-joint disease, Pott's disease, gout, rheumatism, sciatica and various other affections, and it is stated that in some instances as high as \$5,000 has been paid for a pair of these wonderful boots. The attention of Mr. Andrews, counsel for the Society, was first called to the practices of the defendants a short time since by the mother of a nine-year-old boy suffering from hip-joint disease. She had been induced to consult "Professor" Hilgert for her son, and under his treatment he had grown steadily worse, until he is now in a very critical condition. The complainant in the present prosecution is the father of a little girl suffering from spinal disease who has been for some time under Hilgert's treatment.

Obituary.

ERNST ZIEGLER, M.D.

IN the death of Prof. Ernst Ziegler, which occurred recently, scientific medicine loses a valuable exponent. He was born in the neighborhood of Berne, Switzerland, in 1849, and studied medicine at Berne and also at Würzburg, finally taking his doctor's degree at Berne in 1872. He soon after qualified as privatdozent at Würzburg and after remaining there three years went to Freiburg in Breisgau as assistant and later as extraordinary professor. In 1881 he filled the chair of pathology and morbid anatomy at Zürich, in 1882 he went to Tübingen in a similar capacity and in 1889 returned to Freiburg, where he remained as professor of pathology up to the time of his death.

He was a prolific writer and investigator, concerning himself particularly with the subjects of tuberculosis, inflammation, neoplasms and rickets. This work may be found in various periodicals and gathered together in systematized form in his well-known textbook on general and special pathology, which was first published in 1881. It is through this latter work that he is chiefly known to American students. An excellent English translation has been in use for a number of years and as a comprehensive textbook of general and special pathology, the work has maintained the high place which it gained for itself immediately upon its publication. Ziegler was an unusually prolific contributor to medical periodical literature, and was the editor of two of the most important publications on pathology in Germany, the *Beiträge zur allgemeinen Pathologie und pathologischen Anatomie* and the *Zentralblatt für allgemeine Pathologie und pathologische Anatomie*. At the time of his death he was engaged in the revision of the special pathology of his textbook, which it is said is so far advanced that with slight further revision it may be printed as essentially the final expression of his opinion. He was popular as a man, lucid as a lecturer, and for many years had gathered about him students from the most diverse countries.

Miscellany.

A TRIBUTE TO PROF. E. S. WOOD.

The following tribute to the late Prof. E. S. Wood, of the Harvard Medical School, is taken from the annual report of the president of Harvard University:

Edward Stickney Wood, professor of chemistry in the Medical School, died on the 11th of July, 1905, in the sixtieth year of his age. Dr. Wood was appointed assistant professor of chemistry in 1871, and at the end of his five-year term as assistant professor he was promoted to be full professor, being at the time thirty years old. He had received a very thorough training in medicine, having cherished a definite purpose to be a physician even before his entrance into Harvard College. When he entered on his duties as assistant professor, the Medical School was supplying instruction in general chemistry, and Professor Wood for years gave much of this elementary instruction; but he gradually developed valuable courses in medical chemistry proper, and before his death had seen all the resources of his department in the school devoted to that subject. As a teacher he was clear, systematic and convincing. He bore a large part during the last thirty years in improving the teaching of chemistry as applied by medical practitioners and health officers, and he repeatedly served on public commissions in which a medical and chemical expert was needed. His most useful public service, however, was as an expert witness in murder trials. He had a remarkable knowledge of poisons and of the means of detecting their presence in the human body

and had also made a very careful study of blood stains. As a witness he was quiet, imperturbable, and evidently concerned only to declare the truth. His character, quite as much as his knowledge and skill, lent weight to his testimony. His professional career covers a period during which the chemical means of diagnosis in disease were greatly enlarged and improved. The new means Professor Wood placed before the successive classes of medical students with steady earnestness and success.

SOME OBSTETRICAL METHODS PRACTISED IN THE PHILIPPINES.

WILLIAM DUFFIELD BELL says that the belief that the women of semicivilized races escape many of the pangs of childbirth is certainly erroneous regarding the Philippine natives. The life of the Filipino woman is comparatively short, due to her many pregnancies, much manual labor, insufficient food, and, most of all, to the crude, brutal and ignorant practices employed as obstetric aids. The two chief procedures used to facilitate expulsion of the fetus consist first, in a stout band of cloth passed about the woman's abdomen and pulled tight by four persons, who are seated, two on each side of the patient, with their feet against her body, and second, in a plank six or eight feet long by a foot wide, which is placed across the woman's abdomen while another person, mounted on the plank, rises on his toes and lets the heels descend forcibly. The birth of the child is followed by the expulsion of the placenta by the above means, and, should the process be delayed, forcible traction on the umbilical cord is made to such an extent as to tear away portions of the placenta, and often large sections of this body are left to find their way from the uterine cavity of their own accord. Weeks and even months later the results of such practice are noticed in the septic conditions which would naturally follow retention of the membranes. The author gives some statistics showing the frequency of complications attending or following this crude midwifery, and then describes a case of imperforate hymen in a young girl. On account of the tumor caused by the accumulated blood she was supposed to be pregnant and was subjected to both the cloth and the plank treatment. She was then brought to the author, who incised the occluding membrane and liberated two quarts and four ounces of thick, offensive menstrual blood. *Medical Record*, Jan. 27, 1906.

THE ARCTIC CLIMATE

F. S. S. Washington, D. C. (*Journal A. M. A.*, Feb. 3) describes and illustrates by a chart and photographs the advantages of the arctic climate for the relief of chronic affections, particularly tuberculosis. The continuous sunshine and its marked effect on animal and vegetable life in these regions during the summer months as

well as its increased actinic quality, the dustless and germ-free atmosphere, and the effect of the sea air under these conditions are all noted as factors in causing the special salubrity for respiratory affections. He sums up the merits of the arctic climate for this class of cases as threefold: "First: It holds absolutely nothing to add fuel to the existing flame. There is no dust to irritate tissues already struggling against a present mastery of the disease, no superadding of pus or other infections, no contracting of colds to invite a setback, nothing to depress vitality. Second: It holds every incentive to an increase of bodily vigor. Each and every chance and opportunity for a cure which is here sought for and obtained only singly and indifferently is there grouped together in full intensity without the necessary presence of any disadvantageous element. Third: As a result of this dual combination, a beginning tuberculous process may be checked in the shortest space of time, and not so much local damage will be done, while waiting for the tide to turn and recovery to begin. This will lessen the chances of a new infection occurring after a cure." He believes there is a chance here for benevolent enterprise with a surety of results.

INTERNATIONAL LARYNGO-RHINOLOGICAL CONGRESS.

TÜRK AND CZERNIAK'S MEMORIAL FESTIVAL, VIENNA, 1908.

FROM the Wiener karyngologische Gesellschaft we receive the announcement that, as in 1908 fifty years will have passed since the clinic of laryngology and rhinology was established in Vienna by Türk and Czerniak, it may be taken for granted that all specialists belonging to this branch in every country will place great value on the fact that this fiftieth anniversary of an event which will always have a lasting effect upon medical science should not be ignored. Influenced by this conviction and also by local patriotic feeling the Wiener karyngologische Gesellschaft has formed the resolution of organizing in the Easter week of 1908 (*i. e.*, from Tuesday the 21st until the 25th of April, 1908) an "international laryngo-rhinological congress," in Vienna. On this festive occasion the society will avail itself of the opportunity for celebrating in a suitable and fitting manner its fifty years jubilee. Other laryngological societies are invited to take part in the congress by sending delegates.

Correspondence.

THE AMERICAN SOCIETY OF SANITARY AND MORAL PROPHYLAXIS.

Boston, Jan. 25, 1906.

Mr. Editors: We all know the proved success of a well-organized and actively and intelligently prosecuted campaign of education as a means of preventing a contagious disease, as exemplified by tuberculosis.

I wish to ask the progressive physicians of Massachusetts a question that a good many may have asked themselves already: Would not a campaign of popular education prevent the venereal diseases as it has tuberculosis? If we think it would, is it not our duty to organize and foster such a campaign? It seems to me that we need consider but three sets of facts before deciding to start such a campaign. *First:* The venereal diseases are a menace to society even greater than tuberculosis on account of their much greater prevalence, and the fact that by causing sterility, abortion, still-born and blighted children, who do not live to grow up or, still worse, beget tainted and degenerate offspring, they are the strongest agents in the world to-day for race suicide and race degeneration.

Second: The false ideas on sexual hygiene almost universal among young people, their complete ignorance of the deadly nature of venereal diseases and their great prevalence, and particularly the general belief of young men that sexual intercourse is a necessity for vigorous manhood,—all this dense ignorance of sexual truth among the youth of both sexes is one of the chief causes of their reckless indulgence in promiscuous intercourse and so of their contracting venereal disease. This ignorance is clearly due to the fact that our present system of education both at home and at school is so incredibly stupid that we leave our children in total darkness concerning the laws governing their most vital and fundamental function, reproduction, and let them pick up and believe any lies and morbid ideas on sexual matters that they may find on the streets and from quacks' and patent medicine advertisements. Fournier, the great French syphilographer, Dr. Morrow of New York, and a great many other authorities on venereal diseases have declared that true education of the young in sexual hygiene, which among other things would teach young men that sexual intercourse outside marriage was not at all necessary for vigorous health, but on the contrary inimical to it because of the great danger of injury from excess and from venereal disease,—that such teaching would be the most effective means possible of preventing venereal disease.

Third: Before this much needed reform in education can be introduced, the medical profession, which alone sees the necessity of it as yet, must awaken the teachers, the clergy, and all intelligent people to demand it; and it is clearly the duty of the physicians to do this service to society.

Can there be a single citizen of Massachusetts, be he a physician or not, aware of the terrible results of these diseases, especially in marriage, and the great number of wholly innocent women and children who are struck down by them, who is not ashamed that his state and country allow these horrible scourges to ravage her citizens unchecked? Will he not demand that these plagues be fought in every possible way, and will he not be ready and eager to help in educating the people, especially the young who are in the greatest danger, concerning the true nature of these diseases and the only sure way to prevent them?

Taking it now for granted that we want to educate the people in sexual hygiene and disease, how shall we set about it? Fortunately we have the example of France to look to, where for many years there has been an organization founded for this very purpose by the leading physicians of Paris and called "The Society of Sanitary and Moral Prophylaxis." This society has the active support of Fournier and all the other specialists in venereal diseases in Paris and also a great many prominent men throughout France among both physicians and laymen; it holds frequent meetings, and publishes a monthly bulletin. It has also published a number of educative pamphlets written in simple language for the working-class young men and women. The Boston Medical Library has this monthly bulletin for 1904, in which you may find a full account of the work and methods of this society. There are such societies also in Germany, Holland and other European countries, all having the same name, the same aim, and the same or similar methods. Two international congresses for the prevention of syphilis and venereal diseases have been held at Brussels; every nation of the civilized world was represented. At the last meeting of this congress the delegates decided to organize societies in every country where they did not already exist, to be called Societies of Sanitary and Moral Prophylaxis. The object of these societies should be "to

study the best means of every order — moral, legislative and social as well as medical — to be employed in the prevention of these diseases."

Dr. Prince A. Morrow of New York, an eminent specialist in genito-urinary diseases, whose recent book on "Social Diseases and Marriage" you may have read, was delegated by this congress to form one of these societies in the United States. In spite of Dr. Morrow's high standing and great influence among his colleagues and also with other leading men in New York, he found such a general lack of appreciation of the importance of the subject, and fear of injuring one's standing by identifying oneself with such an unmentionable subject, that it was only with the greatest difficulty, and by continually laying stress on the humanitarian side of the problem that he and his co-workers finally succeeded in enlisting the support of one hundred and twenty-five of the best physicians in New York, and a few broad-minded and humane clergymen and laymen, and founded last February the American Society of Sanitary and Moral Prophylaxis.

I can best show you the aims of this society by quoting some of the articles from its constitution:

ARTICLE I. The headquarters shall be located in the United States with branches in other cities of the United States.

ARTICLE II. The object of this society is to limit the spread of diseases which have their origin in the social evil. It proposes to study every means — sanitary, moral and administrative — which promises to be most effective for this purpose.

ARTICLE III. This society is to be composed of members of the medical profession and of the laity, including women.

Let me supplement these extracts by a few quotations from Dr. Morrow's inaugural address. "In answer to the question continually asked of members of the society, 'Do you aim at the regulation of vice?' he says, 'This society does not embrace in its objects the legalization or prostitution or the sanitary surveillance of prostitutes with a view to making prostitution safe. Prostitutes should be treated and cured, if possible, like all victims of these diseases; but the state, in issuing a certificate of health which is equivalent to a license to practise this vocation, proclaims the doctrine unhygienic as it is immoral that debauchery is a necessity for men.' The key to the solution of this problem is not to make prostitution safe, but to prevent the making of prostitutes. From this point of view the study of the underlying causes, the bad social conditions, of which prostitution is largely the product, would properly come within the scope of this society's work."

"The evil of prostitution can never be corrected so long as the morals of young men are considered a negligible quantity, and the 'sowing of wild oats' is recognized as a harmless and pardonable pastime."

Such in outline are the aims and spirit of the American Society of Sanitary and Moral Prophylaxis. It holds meetings twice a month at the Academy of Medicine in New York. At the meeting on Dec. 14 four papers were presented as follows:

1. Should education in sexual matters be given to the great body of the young men of the working classes? — F. Duncan Huley, M.D.

2. Should this instruction be individual or collective, through pamphlets, tracts, lectures, talks to young men, etc.? — Rev. John J. Wayne, S. J. and Prof. E. N. Searley of the International Y. M. C. A.

3. What social groups and agencies whose work brings them in direct contact with the living conditions of the people may be utilized for this educational work? — Dr. David Blaustein, superintendent of the Educational Alliance.

4. Should this education be extended to the young women of the working classes? — Margaret Claverie, M.D.

These papers were followed by a general discussion by prominent members of the laity and medical profession.

It seems to me that this society in New York has shown us physicians of Massachusetts very clearly how to set about this delicate and important task of educating the public concerning sexual hygiene and diseases, and that we should lag no longer behind our more progressive colleagues, but follow their good example by getting together

and organizing a Massachusetts branch of the American Society of Sanitary and Moral Prophylaxis without delay.

All physicians of this state who respond to this appeal, and wish to help in the organization of a branch of the American Society here in Boston, will help greatly toward that end by sending their names and addresses to the writer at 87 Montclair Avenue, Roslindale, Mass.

Very truly yours,

Wm. L. Holt, M.D.

CHARLES E. BUCKINGHAM, M.D. "ERRORS IN THE HARVARD MEDICAL SCHOOL HISTORY."

AN ANSWER TO THE AUTHOR OF THE HISTORY.

Boston, Feb. 5, 1906.

Mr. Editor: A letter of mine in the *JOURNAL* of Jan. 25 has called out one in the issue of Feb. 1 from Dr. T. F. Harrington, the author of the History of the Harvard Medical School. If I understand him, he disclaims the offensive meaning which I had put upon his words in the biography of the late Charles E. Buckingham. So far, this is satisfactory. As his words were understood by others as they were by me, it seems proper that he should place an explanatory note on page 867 in such copies as are still unsold.

The other correction that I made was in the article on the *Boylston Medical School*. My sole aim was to show that that school was not injured in any degree by the withdrawal of Dr. Buckingham, because he did not withdraw, and that his relations with Harvard did not affect the *Boylston School* because they did not begin until ten years after its close. This I showed by facts, dates, references. In return, I got generalization, assertion, absence of proof, and there is now introduced, not the statement but the wholly unwarranted implication that there was some relation between him and Harvard previous to his election by the Corporation. This is not true. I it means anything, it means that he gave instruction to Harvard at the House of Industry. But he resigned from that hospital within a few weeks from the time when the *Boylston School* closed, as is shown by his publishing cases in your *Journal* of April 12, 1855, as "formerly Physician to the House of Industry."

He gave some clinical lectures at the Boston City Hospital when that was opened, nine years later, but they were not for any school. He himself told me that it was after these lectures that he was offered a Harvard appointment, and that in view of the possible results, he had seen fit, before accepting, to consult the then new City Hospital staff.

I think that the author should therefore make a correction on page 505.

Very truly yours,

EDWARD M. BUCKINGHAM, M.D.

OPEN-AIR TREATMENT OF TUBERCULOSIS.

SOUTH BOSTON, MASS., FEB. 4, 1906.

Mr. Editor: The title to Dr. T. F. Harrington's recent paper, "Open Air Treatment of Tuberculosis," in the *Wellfleet Convalescent Home*, with a list of Dr. Harrington's Permanent Cured Cases, published in the *JOURNAL*, is misleading. One would naturally infer from it that the cases reported were treated by the open-air method and in the *Wellfleet Home*. In point of fact, none of the cases were treated by the open-air method in the *Wellfleet Home*. However, the *Journal* of the *American Medical Association* has been misled by taking it for granted that the above cases were treated in the *Wellfleet Home*, and it is regrettable that the leading journal in the current literature of medicine has been misled in this manner. The *Journal* of page 385, Dr. Bradley's paper on tuberculosis, is correct, and it is regrettable that it is so easily misled by error.

Very truly yours,

EDWARD A. LEE, M.D.

SOCIETY NOTICES.

BOSTON MEDICAL LIBRARY MEETINGS IN CONJUNCTION WITH THE SUFFOLK DISTRICT BRANCH OF THE MASSACHUSETTS MEDICAL SOCIETY.—Medical meeting, Wednesday, Feb. 14, 1906, at 8.15 p.m., John Ware Hall. Subject: "The Military Hygiene of the Japanese Army," Capt. Charles Lynch, United States Army. Military Surgeons are especially invited to attend. Light refreshments will be served after the meeting.

GEORGE W. GAY,
ELLIOTT P. JOSLIN,
JOSHUA C. HUBBARD,

Committee on Medical and Social Meetings.

NEW ENGLAND HOSPITAL MEDICAL SOCIETY.—The regular meeting of the New England Hospital Medical Society will be held at Hotel Nottingham Thursday, Feb. 15, at 7.30 p.m. Section of Pediatrics. Dr. Mary F. Hobart, chairman. Paper, "Tetany in Young Children in America," by Dr. Annie S. Daniell, formerly Professor of Pediatrics in the Woman's Medical College of the New York Infirmary.

BLANCHE A. DENIG, M.D., Secretary.

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING FEBRUARY 3, 1906.

G. ROTHGANGER, surgeon. Detached from the naval hospital, Norfolk, Va., and ordered to the naval hospital, New York, N. Y.

A. FARENHOLT, surgeon. Detached from the "Raleigh" and ordered to the "Oregon."

G. F. FREEMAN, passed assistant surgeon. Detached from the naval station, Cavite, P. I., and ordered to the "Raleigh."

L. H. WHIFLER, assistant surgeon. Ordered to the naval station, Cavite, P. I.

P. M. RIXEY, surgeon general. Commissioned surgeon general and chief of the bureau of medicine and surgery, Navy Department, with the rank of rear admiral, from Feb. 5, 1906.

JAMES D. GATEWOOD, surgeon, U. S. Navy. Designated by the acting secretary of the Navy is detailed as a member of the joint board of medical officers of the army and navy, appointed by orders of Jan. 11, 1906, War Department, to consider improvements in the first aid dressings and uniformity of equipment for the medical departments of the two services, vice Surgeon CHARLES F. STOKES, U. S. Navy, relieved. War Department, Jan. 21.

BOOKS AND PAMPHLETS RECEIVED.

A Case of Visual Hallucinations and Crossed Amblyopia with Vascular and Degenerative Lesions in the Calcarine Cortex and Other Portions of the Occipital Lobe; also with Atrophy of the Pregeniculate and Optic Tracts. By Charles K. Mills, M.D., and C. D. Camp, M.D. Reprint.

The Principles of Bacteriology: A Practical Manual for Students and Physicians. By A. C. Abbott, M.D. Seventh edition, enlarged and thoroughly revised. Illustrated. Philadelphia and New York: Lea Brothers & Co. 1905.

The Cure of Femoral Hernia. Results of One Hundred and Ten Operations by a Single Method. By William Burton de Garmo, M.D. Reprint.

Report of the Surgeon-General of the Army to the Secretary of War for the fiscal year ending June 30, 1905. Washington, D. C.

Manual of Operative Surgery. By John Fairbairn Binloe, A.M., C.M. (Aberdeen). Second edition, revised and enlarged. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1905.

A Manual of Diseases of the Nose and Throat. By Cornelius Godfrey Coakley, A.M., M.D. Third edition, revised and enlarged. Illustrated. New York and Philadelphia: Lea Brothers & Co. 1905.

Mt. Sinai Hospital Reports. Volume IV. For 1903 and 1904. Edited for the Medical Board by N. E. Brill, A.M., M.D.

On Becoming Blind. Advice for the Use of Persons Losing their Sight. By Dr. Emile Javal. Translated by Carroll E. Edson, A.M., M.D. New York: The Macmillan Company. 1905.

Manual of Chemistry. A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Text-Book Specially adapted for Students of Medicine, Pharmacy and Dentistry. By W. Simon, Ph.D., M.D. Eighth edition, thoroughly revised. Illustrated. Philadelphia and New York: Lea Brothers & Co. 1905.

A Treatise on the Nervous Diseases of Children for Physicians and Students. By B. Sachs, M.D. Second edition, revised. Illustrated. New York: William Wood & Co. 1905.

Hygiene and Public Health. By B. Arthur Whitelegge, C.B., M.D., B.Sc. (Lond.), F.R.C.P., D.P.H., and George Newman, M.D., D.P.H., F.R.S.E. New edition, revised, enlarged and in great part rewritten. Illustrated. Chicago: W. T. Keener & Co. 1905.

A Manual of Chemistry, Inorganic and Organic. Covering the Syntheses of the Conjoint Board and the Society of Apothecaries. By Arthur P. Luff, M.D., B.Sc. (Lond.), F.R.C.P., F.I.C., and Frederic James M. Page, B. Sc. (Lond.), F.I.C. Third edition, revised throughout. Illustrated. Chicago: W. T. Keener & Co. 1905.

Clinical Methods. A Guide to the Practical Study of Medicine. By Robert Hutchison, M.D., F.R.C.P., and Harry Eady, M.A., F.R.C.P. (Ed.) F.R.S.E. Ninth edition. Illustrated. Chicago: W. T. Keener & Co. 1905.

Dissecting Manual Based on Cunningham's Anatomy. By W. H. Rockwell, Jr., M.D. New York: William Wood & Co. 1905.

A Text-Book of Practical Therapeutics, with Especial Reference to the Application of Remedial Measures to Disease and their Employment upon a Rational Basis. By Hobart Amory Hare, M.D., B.Sc. Eleventh edition, enlarged, thoroughly revised and largely rewritten. Illustrated. Philadelphia and New York: Lea Brothers & Co. 1905.

Transactions of the Maine Medical Association. Vol. XV. Part II. 1905.

The Indiana University Bacterial Culture Chart.

Operative Surgery. For Students and Practitioners. By John J. McGrath, M.D. Second edition, thoroughly revised. Illustrated. Philadelphia: F. A. Davis Co. 1906.

Anatomy and Physiology for Nurses. By LeRoy Lewis, M.D. Illustrated. Philadelphia and London: W. B. Saunders & Co. 1905.

A Text-Book of Physiology for Medical Students and Physicians. By William H. Howell, Ph.D., M.D., LL.D. Illustrated. Philadelphia and London: W. B. Saunders & Co. 1905.

Treatise on Diseases of the Skin. For the Use of Advanced Students and Practitioners. By Henry W. Stelwagon, M.D., Ph.D. Fourth edition, thoroughly revised. Illustrated. Philadelphia and London: W. B. Saunders & Co. 1905.

A Manual of the Diseases of Infants and Children. By John Rührh, M.D. Illustrated. Philadelphia and London: W. B. Saunders & Co. 1905.

The Vapor Method of Anesthesia. By James T. Gwathmey, M.D. Reprint.

The Cost of Modern Hospitals. By S. S. Goldwater, M.D. Reprint.

Address.

THE PROBLEM OF PSYCHIATRY IN THE FUNCTIONAL PSYCHOSES.

BY EDWARD COWLES, M.D., BOSTON.

(Concluded from No. 6, p. 152.)

MENTAL PHYSIOLOGY AND THE FUNCTIONAL PSYCHOSES.

THE true basis of a pathological physiology in psychiatry is mental physiology and its physical correlations of function; variations of nervous and mental reactions in their initial stages may be wholly functional. Approaching the subject newly from this point of view the physician is assumed to know the modes of reaction of the nervous and mental mechanisms and that part of the work done by the nervous system leads to consciousness; he should know also the primary postulates of psychology. Having to study the operations of other minds, he needs to distinguish, in descriptive terms, his own conscious experiences.

A helpful method in psychiatry is to separate the experiences that relate to the outer world from those that belong to the inner life. Professor Sanford presents this idea in discussing the relation of psychology and physics, to which reference has been made. He describes the conscious experiences that may be called physical phenomena: percepts or series of percepts belonging chiefly to the sense-fields of sight, hearing and touch, including under the latter the kinesthetic senses, as well as pressure, heat and cold; he speaks of these as the senses that mediate the "life of relation" with the world outside our own bodies, — the "physical group of senses." Taste, smell, pain, the general and organic senses — all having little external reference — are not mentioned at all in physics, except incidentally. The method of psychology, on the other hand, while not essentially different, has broader outlines; its phenomena are various conscious experiences, including all those with which physics sets out, but also experiences involving pain, organic and general sensations, feelings, emotions, memories, images, volitions, processes of reasoning, and everything that belongs to such experience. Physics, dealing with outer experiences only, practically works with terms derived exclusively from the kinesthetic and a part of the dermal and visual experience in its spatial function; these are the senses capable of perceiving matter in motion, and the physicist in using their terms excludes reference to the other senses of the physical group, — sight, hearing and touch. Psychology deals with both inner and outer experiences.

This general view of mental physiology has a special value for psychiatry which it is possible here only to indicate. The conception of a relation between conscious experiences and outer physical phenomena implies an organism, with its special "physical group of senses" in touch with the outer contacts, acting as a medium of transmission between the two; this medium may be

conceived as forming also a *somatic group of senses* in the paths of communication. But this mechanism of transmission does not afford, even normally, open ways without friction or obstruction; to its report of contacts with the outer "life of relation" it adds the multitude of returns with all their variations from its own physical workings, and for this process the same mechanism of kinesthetic and other senses, in a new grouping with others, including the organic and general sensations, is used. In abnormal as well as normal conditions these returns, however imperfect, stand for the truth and the whole truth in conscious experience; in health we think as little as possible of the medium of transmission, and in all conditions of well-being or ill-being we can only describe our organic feelings in general terms. We do not recognize for the most part the sources of these sensations, yet they have a controlling influence upon our minds. These considerations indicate three groupings of the functions of the sensory mechanisms of conscious experiences: (1) The physical group of senses of the outer "life of relation"; (2) the somatic group of senses of the inner life — our conscious experiences of our own bodies; (3) the central psychical life which includes both of the other groups of conscious experiences besides those belonging distinctly to its mental aspect. The interest of this to psychiatry is that comparatively little attention has been given to this inner sensory field of the sources of conscious experiences; yet, it may be said, here are the conditions and the very material of bodily and mental stimulations and sensations with which the mental work is done. These explaining principles have been almost wholly omitted from the accepted formulae of the conceptions of modern advanced psychiatry which has chiefly concerned itself with the motor aspects of mental life and expression. These physiological references are needed to explain many of the symptoms of the psychoses and should have their full value in the formulation of the principles of mental physiology and psychiatry.

A functional conception of mental pathology²⁴ directs observation to the first and smallest departures from normal action, upon the principle that all variations of a pathological character are subject to the laws of normal function acting under abnormal conditions. The study of the development of symptoms is equivalent to noting the genesis and progress of the conflict between the functional energies and the abnormal conditions. Functional modifications, as symptoms, are the results of changes of action; organic effects are the results of changes of structure. The genetic method, the sequences of functional phenomena are noted in the functional psychoses; there are variations of function, therefore,

²⁴ Harker, L. L. *Method in Medicine*. Boston, Mass., 1903. See also *Journal of the American Medical Association*, June 20, 1905. Reference is made to a functional method of study, here it is noted that the functional method is being more widely used, and that the descriptive classification of the symptoms of the psychoses is being replaced by a classification of the functional phenomena. The author is indebted to an address by the Mr. M. J. Harker, published while this paper was in manuscript.

manifested by its reductions and recoveries. The following characterization in outline of the psychoses is an application of the functional principles referred to in the foregoing pages. For the purpose of tracing the several orders of symptom-factors from their genesis in functional sources they can be considered most simply under the divisions of the mental elements — intellect, feeling and will, as these terms are used in modern psychology for purpose of classification.

1. THE FUNCTIONAL PSYCHOSES. A study of the large group of cases of non-deteriorating mental disorder yields certain general conclusions as to what may result to the normal well-endowed individual when subjected to the effects of use, disuse, overuse and stress. Beginning with the least degrees of decline of functional vigor, below normal fatigue, there is no point in the declension where a line can be drawn definitely marking a change from one named "clinical type" to another, down to the lowest degrees of vital energy and complete loss of volitional function. Throughout all observations of these changes the essential principle of variations of irritability is never to be lost sight of, nor the fact that the first step toward deterioration of function is characterized by a rise of irritability. Another pervading principle is that among the multiple functional mechanisms failure of energy is unequal, and that changes and losses of irritability must apply as much to sensory as to motor function. The word "psychosis" can be used most profitably as correlative with "neurosis," and as including both its proper psychological and pathological meanings leaving the differentiations of sanity and insanity to be indicated by these words. A basis of inquiry, as above described, prepares the way for the examination that comes first in order of the initial departures from mental integrity, viz.: The affections called imperative and fixed ideas, and the primary asthenic conditions of neurasthenia before the after-effects of chronic states have supervened.

Insistent and fixed ideas refer to a wide range of kindred cases of affections that can happen to sound minds in persons neither temporarily nor constitutionally neurasthenic. The functional elements are normal and the affections may attain characteristic forms in normal minds; but this happens to them more readily when there is neurasthenic reduction of inhibitory energy and greater degrees of intensity and persistence occur in association with constitutional instability. All observant sane persons estimate the purposes of others by interpretations of their speech and behavior, and thereto fittingly adapt their own conduct influenced by inferences and judgments in a manner that would indicate "paranoid" suspicion under certain circumstances. Inasmuch as this is a universal, functional, self-protective principle, sane persons have normally the functional disposition to produce ideas of suspicion and persecution, but well-balanced minds control thought and speech. In *any psychosis*, however, associated with asthenic conditions there may be "paranoid forms" not belonging to that psychosis as essential to the symptom-complex; this reaction is liable to become casually intensified or further developed and fixed by habit. In many cases not "psychasthenic," nor physically neurasthenic, the affection is purely a functional accident; it may involve all forms of emotional reactions, other than "phobias," and many cases recover.

Neurasthenia, in its early conditions, uncomplicated by the effects of habit, presents the same elements, in mild degrees of functional reduction, that characterize

their greatly varied combinations in the symptom, complexes of the graver conditions of melancholia, mania and exhaustion psychosis or confusional insanity. These neurasthenic conditions may occur in all persons, under sufficient stress, but when there is constitutional weakness the power of resistance is less. The functional elements of the organism, all working together, constitute combinations of community work of extreme complexity; these elements being unequally reduced in efficiency the "clinical types" are very much varied. A method of analysis of symptoms with the endeavor to estimate their functional values and their relations to their physiological sources will appear under the following topics.

The functional psychoses constituting the main group of non-deteriorating affections pathologically regarded as insanities, all have a basis of some kind or degree of asthenic reduction of functional efficiency; as already indicated, these may include the whole range of degrees from simple cases of nervous exhaustion downward through the simple and pronounced cases of melancholia and mania, including all varieties of phases and combinations of the symptom elements; also including the more actively induced exhaustion psychoses and confusional deliria. Functionally considered, it is proper to regard all these cases as "functional psychoses" until proved to the contrary. Function comes first as the present criterion; organic change is a result. Cases carefully diagnosed characteristically tend to recovery. The designations, neurasthenia, melancholia, mania, etc., are simply valuable descriptive terms; they are thus not correct names of diseases as clinical types, and we have yet to study broadly the genesis and development of these conditions. By the functional method we have merely advanced, as yet, little beyond the general fact that two classifications may be made of the psychoses, — the non-deteriorating and the deteriorating. By the morphological, clinical-type method there is a singular lack of success in adopting principles of valuation of symptoms by which men of good minds can reach like conclusions. We are not yet ready to determine species; this should be aided by the study of the genetic character of the symptom elements.

The significance of the unifying characters of the non-deteriorating range of psychoses may be made much clearer by grouping them according to the functional sources of the symptoms and their own natures. The symptom-factors thus fall into natural groups, which should be studied with complete freedom from preconceptions of "disease-forms." No more is attempted here than to harmonize these groups with the elementary postulates of psychology, and with the general physiological facts heretofore cited.

(1) Feeling. — (The feelings and emotions.) The emotional variations that are pathologically persistent are in close relation with the changes of bodily states which are represented in the central nervous system by the organic, kinesthetic and general sensations: the sum of these has, physiologically, a strong influence upon mental feeling, and therefore in pathological conditions the emotional tone of the psychical sphere corresponds with the sense of personality by "states of mental depression" (melancholia) associated with malaise and ill-being, and "states of mental exaltation" (mania) with sense of well-being and false euphoria. The complex sources of the sense of body have been described and the changes of irritability due to fatigue and other causes; the consequent variations of the sense of physical pleasure and pain are closely connected with the rise and decline of irritability, its intensifications and losses, but not with parallel changes.

In the emotional states of "neurasthenia" the depression is variable; of "melancholia," persistent; in both the feeling-tone may be combined in various ways with the first degree of functional deterioration of irritability marked by agitation, restlessness, "irritable weakness" (psychomotor excitation), or by dullness, slowness, languor (psychomotor retardation). In nervous exhaustion and melancholia the feeling-tone is constantly influenced by bluntings and losses of organic sensation, strikingly shown in the loss of the sense of fatigue — "fatigue-anesthesia," and the various unequally distributed conditions described in the natural order of decline as hyperesthesia, hypoesthesia, paresthesia and anesthesia; also ease and obstruction of motor expression have their reflex influence upon the affective states as in a feeling of facility, or the "sense of inadequacy" and the "sense of effort."² Hopelessness, introspection, retrospection, apprehension, self-reproach, are logical consequences. All these variations are persistent intensifications and differences of the normal connections of ideas and emotions, with their correlated physical reactions; the persistence of morbid emotional reactions indicates deteriorated body states.

In the emotional states of "mania" there is the characteristic exaltation and exhilaration; but in many cases there is depression of feeling of the type shown by anger in its origin from painful states of irritation, and by distressing delusions and aggressiveness. These two prominent types of feeling-tone are associated with corresponding variations of irritability marked by its rise from moderate to high degrees of psychomotor excitation, shown mentally in "flight of ideas," corresponding to the agitation and irritable weaknesses in melancholia, — sometimes more extreme and sometimes reduced and lost. The clinical pictures in some cases may indicate a simple absence of painful irritation, but they certainly show, characteristically, the false euphoria of blunted sensations, as in alcoholic intoxication.

(2) *Intellect.* — (Sensations — perceptions and ideas.) The "thinking process," as it is rather vaguely called, may be definitely conceived to include the ideational reactions of the stream of consciousness, constituted of the association processes in combination with the inhibitory or exciting control of the will working through attention and apperception; the emotional factor enters into the combination and modifies the "thinking process" with intensifications of interest and motive influences. It is impossible to describe these function factors separately because they all work together. The character of the ideas, the sensations revived by memory in the association process, whether depressed in melancholia, or exalted in mania, is in harmony with the emotional tone as it is "lowered" or "exalted." The time element in the processes of the stream of consciousness varies with the rise in irritability and especially with the coincident reduction of inhibition. This, in mania, with the intensification due to irritability, produces "flight of ideas" with quick reactions and superficial associations. The tendency is to increasing weakness, reduction of clearness, incoherence and final arrest of mental functions in confusion or stupor. With disordered perceptions there are illusions and hallucinations; delusions arise. Maniacal states represent graver degrees of derangement than melancholia, and a lower level of functional reduction, especially of inhibition. The more profound conditions of acute exhaustion (confusional insanity, exhaustion psychosis) occur sharply by themselves from strongly exhausting influences and are varied

manifestations of delirium; these may supervene in the severer types of both melancholia and mania.

(3) *Will.* — (Inhibition — attention and apperception.) In the sense that acts of the will are such acts only as cannot be inattentively performed it produces exciting or augmenting effects in the "thinking process," or inhibiting effects; working through attention and apperception its function of control appears in voluntary inhibition, and this has been described in part in connection with the other elementary functions and in the reference to the physiological law of inhibition. Normally, inhibition, both physiological and voluntary, stands in mobile equilibrium with the tendency of all conscious and neural excitations to discharge into motor effects, open or concealed within the organism. In the incessant change and succession in the train of ideas in consciousness the attention holds the chosen or attracting idea in the interplay of neural processes and thus inhibits its tendency to pass away, other items being held with it in reasoning, and apperception being a special form of the same controlling influence. This inhibitory function is a true index of the integrity of vital energy; it is regularly reduced in efficiency with asthenic reduction of the nervous forces. Voluntary inhibition is variably reduced in neurasthenia, persistently in melancholia, and greatly so in mania with loss in delirium.

(4) *Organic Sensations and States.* — (General and kinesthetic sensations.) The importance has been shown of these function factors of the "somatic group of senses," in respect to the representations they bring into conscious experiences concerning the inner physical life of the body. In health the sensory and motor reactions of our bodies and our conscious experiences are adjusted to contacts with the environment within normal limits: the organic and kinesthetic senses normally contribute to the general welfare with only salutary interferences, and these being mostly unnoticed we habitually ignore their existence. It is in disordered physical conditions that the abnormal influences arise and interfere with and derange the experiences of the mental life; they are general and vague in character, but are of essential significance though only described as subjective experiences. The phenomena of changes of excitability and loss of function may be variously described. An interference with the functions of any one system will disturb the normal functional equilibrium that must of necessity exist in the action of the whole.³ The principle of localized variations of irritability, as in the neurones, applies to all functioning groups of cellular mechanisms; the threshold of excitation may be raised or lowered in any of the sensory, motor or central and psychical parts of the reflex mechanisms. Upon these changes may be predicated all the phenomena of psychosensory and psychomotor excitation and retardation, conditions that appear in some kind or degree in the whole range of the functional psychoses. These variations may be ascribed to reductions of the nutritional maintenance of the vital energies. Hyperesthesia and hyperkinesia are the complementary manifestations that betoken fatigue, or equivalent weakness from some cause, of the physiological inhibitory energy; this condition is often associated with anesthesia of the fatigue sense in the same case.

It should be noted that the changes of feeling tone of motility and of control do not run parallel to each other, hence the differences of the clinical pictures presented by typical melancholia and mania, and the so-called "mixed cases"; melancholia presents two principal types — emotional depression with excitation and retardation; in mania presents emotional excitation

² Cf. Cowley, E. *Op. cit.* *Neurasthenia and its Mental Symptoms*, 1891.

³ Cf. Mott, F. W. *The Degeneration of the Neurones*.

with excitation, and sometimes there are painful states of consciousness and the acute reductions of function in exhaustion and stupor. There are numerous phases in the unified melancholia and mania as constituting one general group of variations of functional disorders presenting clinical phenomena apparently widely divergent as "clinical types," but falling into harmonious relations when explained consistently with their developmental and genetic character.

2. THE DETERIORATING PSYCHOSES. These psychoses have an important relation with the *functional psychoses* that should be mentioned here. They are characterized by persistent functional deterioration and tend to dementia; this is consistent with the opposing fact that the vital energies of the life-process sometimes appear to overcome in recovery the interferences with their normal action. It has been said that the functional psychoses tend to recovery; yet the failure to recover in some cases may be consistently referred to constitutional weakness or the loss of vigor in old age. This does not imply that heredity is an essential cause of mental disease; "neuropathic" persons have less endurance against all adverse influences. Among the *deteriorating psychoses* the first place is given to a large group called "dementia precox"; its general form is not clearly differentiated, nor its special divisions; no common basis is implied in the designations hebephrenia (mental weakness), katatonia (motility disorders), paranoid forms (insistent and imperative conceptions). A single case may change from one "form" to another, and the recognition of some constant characters is required to unify all the "forms"; the common fact of dementia is shown in the deterioration of capacity that may occur in any of the functional mental elements, varied in different cases; this implies structural changes. The character of the failure is revealed in the quiescent states after the subsidence of active symptoms. The most common fact is the deep-seated deterioration of the emotional nature; hence the characteristic indifference and apathy which favors the development of habit automatisms, etc. Concerning this large group of deteriorating psychoses, regarded as above stated, and including also the few other "disease-forms" at present accepted as such, some general conclusions now appear with respect to the functional psychoses.

The unification of the functional psychoses can only be indicated here with respect to the explanations and conclusions reached during some years of teaching the principle that each of the groups conveniently designated neurasthenia, melancholia, mania, etc., simply includes variations in combinations of different degrees of functional disorder of the same physical and mental elements. The essential unity of melancholia and mania was recognized by Griesinger and others with differing explanations; modern physiology and psychology broaden and simplify the whole subject with better explanations of general principles.

In recent psychiatry there is an evident tendency to the unification of the psychoses. A significant contribution has been made by Dana;²⁷ in his large neurological experience he has seen much to favor the idea that most neurasthenias are mental cases, or non-insane psychoses; the term phrenasthenia is used for a special group of neurasthenic or degenerative

psychoses including mainly those described by Janet as psychasthenia; it is said that an innate constitutional weakness underlies all the chief non-accidental functional insanities. There is much reason for a simplifying psychiatric conception, complementary to Dana's view, that not only most, but all, functional mental cases are subjects of asthenic reduction of functional efficiency and are neurasthenic. The tendency is notable in the remarkable studies of Janet in which he reaches the conclusion by psychological analysis that many of the apparently diverse psychoneuroses may be unified under the one principle of psychasthenia; this implies a general and special insufficiency in all the phenomena and is at the same time neurasthenia; these affections represent regular degrees of lowering of functional efficiency.

The genetic method leads to a comprehensive view of all the psychoneuroses. Considered biologically and physiologically neurasthenia, phrenasthenia, psychasthenia and all the functional psychoses are modifications of functional characters. Whether these modifications were acquired newly by the individual himself, or by his ancestor and thereafter transmitted as though they were inherent variations, the problem is essentially the same. However perverted, distorted and anomalous the functional phenomena of vital activity may be, they must be traced back to the first interferences with the physiological elements to find their explanation in their genesis. We may assume that all normal adult individuals are subject to certain acquirable functional modifications,—numerous and complex, thus forming the symptom groups called neurasthenia, melancholia and mania, for example; all abnormal persons are subject not only to the same changes, but to something more and something different, and these additions may be simply special variations of intensity, or degrees of impairment, or of differences pointing to other than functional explanations. A general principle in mental pathology may be derived from these considerations. Whatever the form of a deteriorating psychosis it has its own pathological characters; but superimposed upon these symptom-factors, and relatively superficial, neurasthenic manifestations commonly appear, and there may be episodes more or less transitory, of manifestations of the functional psychoses. This occurs notably in the early stages of dementia precox and manifests the practical concurrence of two diseases, viz.: the permanent deteriorating psychosis and the transitory phases (melancholic, maniacal and paranoid) of the functional psychosis. This principle accounts also for the fact of there being maniacal as well as melancholic types, and the "paranoid conditions," in the "involution psychoses"; this principle is already well recognized in respect to the neurasthenic, melancholic and maniacal modes of onset of paresis; and to the same types of functional disorder, and tendency to obsessing suspicious and delusional ideas, in senile insanity in which active symptoms may measurably or wholly

²⁷ Dana, C. L.: The Partial Passing of Neurasthenia, BOSTON MEDICAL AND SURGICAL JOURNAL, vol. 41, 1904.

disappear. All the psychoses called functional for purposes of classification, and being nearest to normal, constitute the main division of the psychoses (considered as mental disorders); all the psychoses called deteriorating and being exceptions to the others, constitute the minor division. In these the fact that in some particulars the reductions of functional efficiency remain permanently deteriorating constitutes dementia, which implies some form of structural change, though none strictly characteristic has yet been found. The pathological principle here suggested leads to a practical method of analysis of the symptom factors of all possible forms of deteriorating psychoses. The first step is the distinction of the purely functional modifications referable to physiological sources; these relate to variations of the fundamental irritability as explanatory of changes of motility and of the sensibilities and emotional tone, all being comprehended broadly in relation with the "somatic group of senses"; closely kindred with these are the reductions of function of the processes of association, memory, attention, inhibition, etc. Holding apart these phenomena of the main division of psychoses as being included in the functional conception of their pathology, and as explainable through their genetic and developmental character, there remain, of the symptom factors of a deteriorating psychosis, those that point to the causes of the special deterioration. This helps to define the problem of research for anatomical explanations. It should not escape observation that when there is "innate constitutional weakness" in cases belonging to the main group of functional psychoses, special modifications may be noted in the symptom factors, especially of the attention and inhibition element whose reduction is the most constant and characteristic fact of constitutional insufficiency. It is in these conditions that the law of habit has its most potent and perpetuating influence.

The functional psychoses, including those answering to the definition of "a typical form of insanity," present some points of special interest when analyzed in accordance with the method and principles examined in the foregoing pages. Reference has been made to Griesinger's descriptive definitions of melancholia as "states of mental depression" and mania as "states of mental exaltation." During more than half a century these designations have held their places in psychiatry; the search for more satisfactory statements has not been altogether successful. The difference of the emotional tone is the criterion but it is not a wholly true one. The depression in melancholia is consistent because the "somatic senses" retain enough of normal function to report truly to consciousness the fact of ill-being of the body; but in mania the exaltation is not constant, the physical correlatives of the feeling-tone are more disordered by reductions and losses yielding more irritating excitations and in many cases a fictitious sense of well-being. But the "somatic senses" produce other equally important symptom-factors in the changes of

motility; in melancholia with impaired inhibition there are both psychosensory and motor excitations and retardations,—in mania, with graver changes and losses of inhibition, motility is more disordered. The word "melancholia," by long usage and observation of the facts, really stands correctly in the recognition of its meaning all of its well-known symptom factors other than emotional depression; the word "mania" meaning madness, stands equally well for both its emotional variations and its motor excitement. In mania there is graver derangement of the "thinking process" and its "states" are at a lower level of reduction than melancholia. These references though meager serve to show that the terms melancholia and mania are well understood as including a great variety of states of varied combinations and proportions of their symptom factors; besides the many typical cases of each group there are found to be very many "mixed cases." There are many phases, and a two-phase conception to represent the original groups of "states" does not hold good; for example, taking out the emotional depression from one group and the motor excitation from the other, in order to designate the distinction of the phases and to characterize the compound "disease form," leads to the exclusion from it of the very essential psychomotor excitation often associated with the depression in the former group, and to overlooking the significance of the emotional changes in the latter. An adequate study of the "somatic group of senses," as suggested here should help to clarify the whole matter. Compound designations for the unified symptom groups yet suggested do not satisfy the requirements so well as their simple combination in "melancholia—mania." The psychoses cannot be limited to the insanities; we must speak of the "non-insane psychoses," and in psychology the word refers to normal function. It might be said that the first step in the classification of mental diseases discovers two great divisions: *functional insanity and deteriorating insanity.*

This discussion of the thesis that the problem of psychiatry is in the functional psychoses required first an examination of the terms and conditions of the problem. This necessitated an inquiry concerning certain principles and conclusions of the biological and medical sciences that have had a controlling influence in psychiatry. Morphological conceptions being dominant in medicine, it was found also that a number of terms and phrases are so commonly employed in medicine that their use has been compelled in psychiatry, although they embody conceptions and theories inconsistent with its dependence upon functional conceptions of mental pathology. The inquiry having led to the conclusion that the physiology of the life-process is the first recourse for psychiatry in the search for explaining principles, it becomes necessary to be emancipated from all preconceptions. The functional conceptions being framed, and applied consistently with the facts of physiology and psychology, lead to a recognition of the developmental and genetic

character of the functional modifications, and indicate their sources in physiological facts. A clearer idea is gained of the relation of conscious experiences to body states, and of the influence of the "somatic group of senses" in the relations of the conditions of the whole organism to the mental states. The dependence of all functional phenomena upon the processes of nutrition and metabolism for the maintenance of the nervous and mental mechanisms, points to the fundamental importance of pathological physiology and chemistry. Physiological and psychological experiment in the immediate clinical examination of functional modifications shown in symptoms helps to determine the physiological sources of the contributing disorders in the whole body as well as the central nervous system.

The psychiatrist inclined to inquiry finds, in the pursuance of his practical work, that as a physician he must treat the whole body, and that a functional conception of mental diseases leads to treatment. Psychiatry belongs to general medicine, and mental disease like bodily disease is not an entity nor an agency but the result of normal function acting under abnormal conditions; the problem requires the investigation of the developmental and genetic character of functional modifications.

SERIOUS HEAD INJURIES AND THE INDICATIONS FOR OPERATIVE TREATMENT.*

BY B. SACHS, M.D., NEW YORK.

Alienist and Neurologist to Bellevue Hospital; Neurologist to the Mount Sinai Hospital, etc.

I AM deeply appreciative of the honor conferred upon me by the invitation to address the members of this Society. The task is one which I have not accepted lightly, and I fear I shall not be able to meet expectations. Your secretary, or some other person in power, has been kind enough to suggest the pace I was to adopt by sending me a list, not only of the remarkable publications of various members of your Society, but still worse, a list of the papers read before you by many distinguished colleagues from other cities whom you have honored similarly to myself. I cannot hope to vie with many of them in the display of learning, nor do I think it wise to deliver myself of what I might suppose to be a learned discourse.

It has occurred to me that it would be better to lay aside all claims to especial learning and to select for your consideration this evening a subject of general and practical interest, a subject which has forced itself upon me many a time during these past years and which led me to believe that it might not be amiss to discuss personal experiences and difficulties encountered in determining the propriety of surgical interference in serious head injuries.

So far as I can see, the question of operative treatment of skull injuries has been left largely to the decision of the surgeon. The points at issue have been discussed in surgical, and not in neurological textbooks; yet Bergmann concedes that the question, whether or not an operation is to be performed, is dependent, not upon the character of the injury to the skull, but altogether upon symptoms pointing to interference with brain function. I cannot indorse this extreme view. If the vault of the skull, more particularly in the parietal region, is severely injured, if there is evidence of continuous bleeding from the middle meningeal artery, the purely neurological considerations must yield to surgical doctrines. Under other conditions it is the neurologist, or at least the surgeon equipped with neurological skill, whose counsel should prevail.

Everyone of us, I am certain, feels, in view of the great advances in surgical technique, that any surgeon might do the usual laparotomy for appendicitis with promise of success; the chief difficulty is to decide, in a given case, whether or not the operation should be performed. Here, as elsewhere in medicine and surgery, diagnostic acumen seems to me to be of even greater value than ordinary surgical skill. This is just as true of operations upon the head. My own experience in collaboration with a number of the prominent surgeons of the day has taught me that the difficulty was not in doing an operation or in having it done, but to decide whether, in man, woman or child after an injury to the head, the patient would be better off if the skull were opened, and if the chances of life would be greater if we trusted to the surgeon's knife and not to the reparative powers of Nature herself. In view of the excellent paper which Dr. Walton published only a year ago (*Annals of Surgery*, November, 1904) on fracture of the base of the skull, I propose to exclude from special consideration the subject matter which has been so well covered in his paper.

I have been at some pains to discover the surgeon's point of view. He has paid great attention to the character of skull injuries, to the differentiation between the various kinds of fracture, to the attempt to differentiate between fractures and fissures. Fissures have been left largely to take care of themselves. This is no doubt due to the fact that they often cannot be recognized with sufficient accuracy, and if recognized, so long as there is no injury to the scalp and hence no danger of sepsis, surgical interference would be of questionable utility. Very properly surgeons are ready to trephine in every case of depressed fracture of the skull. There can be little doubt that in comminuted, depressed fracture the chances of life are greater if this comminuted fracture is treated in accordance with the most approved surgical principles. Such a purely surgical question it is well to leave entirely in the hands of the skilled and conscientious operator, but I ask what are the symptoms pointing to injury of the brain which are to argue in favor of immediate interference?

*Read before the Boston Society of Psychiatry and Neurology, Nov. 16, 1905.

The surgical writers on this point have had much to say on the distinction between concussion, contusion and compression of the brain. *Compression* from the surgeon's point of view is inferred from disturbances of circulation, while the diagnosis of *contusion* rests upon "microscopically noticeable destruction of brain tissue with extravasation of blood," and *concussion* is supposed to be due to two distinct disturbances; first, in cases recovering rapidly, "to a momentary anemia," and in protracted cases to "a combination of circulatory disturbance with disseminated microscopical contusions." This is the way in which one of the best surgical writers of the day attempts to illuminate the subject.¹

The question arises whether there is any other difference except that of degree between concussion and contusion. In the milder cases, which might be also called cases of simple shock, the disturbance is supposed to be due to momentary anemia; a very difficult proposition to prove or to disprove. But certain it is that while in some instances the symptoms of a sudden and marked anemia may be present, the diagnosis of shock is made innumerable times without the appearance of coma or convulsions, the only symptoms which are at all expressive of an anemia of the brain, if we may trust to the results of experiments on animals. In protracted cases of concussion, the combination of circulatory disturbance with minute evidences of contusion, simply proves that the difference between concussion and contusion is only one of degree and we cannot expect it to be otherwise if we bear in mind the experiments of Schmaus on the spinal cord of animals. The experiments of Koch and Filehne on the brain show that the nervous tissues as such are directly affected and injured as a result of the long-continued infliction of mild blows.

At first the centers appear to be stimulated and then exhausted. Horsley concluded long since that the symptoms which persisted after the effect of the primary shock had disappeared were due to minute hemorrhages. Kocher and others have maintained that the diagnosis of concussion is to be made if there is a sudden development of symptoms indicating a diffuse lesion of the brain with a rapid disappearance of the symptoms. Thus for instance, in a case in which there was complete loss of consciousness with rapid recovery we are to diagnose contusion; the diagnosis of concussion would rest upon symptoms pointing to a circumscribed lesion without loss of consciousness with symptoms pointing to subsequent inflammation in the area immediately surrounding the part injured. But why limit such a term to small areas when a very considerable portion of the brain may be exposed to the injury? I cannot see the logic of this distinction. The brain is supposed to be compressed if, with or without loss of consciousness, all the symptoms become more and more marked

thus indicating a spread of the trouble from the site of the original injury. Kocher insists that in the case of concussion there is naught to do except to prevent further mischief. In cases of contusion the only reason for interference is the desire to avoid permanent focal disturbance, such as paralysis, spasm, epilepsy. In the case of compression there is danger to life; and he adds that any one who does not wish to be guilty of neglect will resort to surgical procedures in every case in which he cannot absolutely exclude the possibility of compression.

The neurologist's point of view is not, and cannot be, the same; he will determine the advisability of operation in accordance with the evidence pointing to the site of the injury; he will also consider whether or not the affected area is within the reach of the surgeon's knife, and above all, will he consider how extensive the injury is; he will also bear in mind the possible reparative powers of the brain itself, knowing how much recovery is possible in hemorrhages into the brain and how much recovery takes place after various inflammatory processes. I do not wish to limit the surgeon's powers of exploiting the brain, or to clip his wings; I am anxious to establish a few principles by which his fortunate therapeutic powers can be directed into the proper channels. The cases which have afforded me the greatest difficulty have been those in which there has been no evident external injury but in which marked cerebral symptoms have developed after the injury. I need not insist on the frequency of injury to the inner table of the skull when the outer surface has remained apparently unimpaired.

The first case I wish to refer to is that of a young gentleman, thirty years of age, whom I had occasion to see in October, 1904, in association with Drs. Kimball and McCosh. He had been hurled from his automobile while participating in a race at eight o'clock in the morning. The chauffeur was killed outright. The patient was seen by a physician soon after the accident, who found him lying on the ground and resting on his elbows. He had been hurled a considerable distance, was stunned, but was able to answer some questions as to his name, residence, where he wished to be taken, etc. He was removed to a hospital a few miles distant, and when he arrived there the physician noticed a slight weakness of the right arm. On his way to the hospital he became more and more drowsy, the stupor increased and after an hour or more he was wholly unconscious and for the first twenty-four hours had to be catheterized. This condition remained practically the same until the next day when I had an opportunity of examining him. There were contusions over both eyes and on the right side of the head and there was a distinct hematoma over the occiput. He was somnolent but could be aroused at the time of my examination (about thirty hours after the accident) and could give his name and address correctly. He stated that his head hurt him, but would fall a sleep as soon

¹ Vid. Bergmann: *System of Practical Surgery*, Vol. I, p. 185, et seq.

as he was left to himself. His hearing was normal. The left pupil contracted more sluggishly to light, the right more promptly, the accommodation reflex could not be tested. All ocular movements appeared to be normal and the fundi were normal. The skull was not sensitive to percussion, but there was a distinct right facial paresis. The tongue appeared to protrude to the left. There was some weakness of the right upper and right lower extremities, the patient using the left leg and the left hand by preference. He was able to withdraw the right leg when tickled or pricked vigorously. So far as could be determined sensations were normal. The right knee jerk was subnormal and this was possibly due to peripheral contusion, for there were present a right ankle clonus and right Babinski reflex. On the left side the knee jerk was normal; but there were no clonus and no Babinski. At the time of my first examination he could be aroused sufficiently to void urine and did so without any difficulty.

From the nature of the accident, the slowly developing but prolonged unconsciousness, the difference in the character of the pupils, and the evident signs of external injury to the scalp, the wisdom of operative relief had to be considered. In view of the fact that the patient's unconsciousness had not deepened into coma, but had been less than it was a few hours after the accident; in view of the absence of fever and convulsive seizures and the improvement that had taken place in the voiding of urine and the improvement in the use of the limbs; in view of the fact that the patient had evidently struck his right side more violently than the left and yet the right extremities were paralyzed, the left uninjured, — considering all these points a favorable prognosis was given and it was decided that no surgical interference should take place unless the patient should become deeply somnolent and unless convulsions should occur and the paralysis become more marked; and more than this, surgical interference seemed altogether out of place; first because there was no sign of serious injury to the skull, and still more because everything pointed to a subcortical and possibly capsular hemorrhage by *contre coup* in the half of the brain opposite to the side to which the skull injuries had pointed.

In the consideration of this case, the question of concussion, of contusion or of compression did not enter.

The only inference of importance was that while the brain had evidently been somewhat injured, the injury was not of the most serious kind or else consciousness would not have shown some signs of returning and the power over the vesical reflex would not have been regained. Moreover, the symptoms pointed to the fact that the lesion was, first of all, a small one; and secondly, that it was situated in a region in which the surgeon could not have reached it even if he had the right to attempt to do so.

This patient made an excellent recovery. For a number of months after the accident he was

weaker in his right extremities than in the left, had some little dysarthria, and the right deep reflexes remained exaggerated. For a long time he was much annoyed by a peculiar form of amnesia, remembering everything up to the time of the accident, but he could not, weeks afterwards, recall his going to the race, taking part in it or being connected therewith. This same limited loss of memory I have noticed in other cases, and it would seem as though the associations had been so rudely disturbed that it required much time for them to be re-established. There is some doubt in my own mind as to whether this loss of memory is ever actually made good, for when the person learns to know later on of the accident and of the occurrences immediately preceding it, it is to be attributed to information subsequently and freely given him by relations and physicians. This loss of memory and of consciousness following upon even slight injuries to the head and brain raises the question as to what actually happened. The effect of the shock is evidently great and the delicate structures of the brain are no doubt thrown into confusion so that the functions of perception and association are instantly destroyed, or at least impaired.

That there are microscopic changes in cells and fibres and not merely circulatory disturbance one cannot doubt, but upon the nature of them it would be useless at this time to speculate.²

In a second somewhat similar case I had also decided that surgical noninterference was the best policy.

The case is that of a young woman who was brought into Bellevue Hospital early on the morning of Oct. 14 in a totally unconscious state. With some friends she had started out about midnight in an automobile to attend the races which were held early in the morning. The person in charge of the machine was evidently under the impression that he had an open street before him, was going at a high rate of speed, and ran the machine into an iron railing.

The car and its occupants were hurled into the opening of a tunnel some ten feet or more below. The patient landed on the opposite side of the tunnel opening at the base of a large stone building, at least one hundred feet from the point at which the car left the street. Strange to say, the other occupants of the car were uninjured, so far as I am informed. The young woman in question was at once brought to the hospital, and on examination by the resident physicians it was determined that she had a very severe contusion of the face and head, chiefly of the left side. The eyes were so much swollen that they could not be opened. There were some blood clots around the eyes and ears, but this was due to external injury and not to blood flowing from within. At the request of Dr. Stewart I was asked to see the patient that day. I found her deeply stuporous yet could be aroused by empha-

² Since writing the above my attention has been called to the excellent studies of W. B. Cannon ("Cerebral Pressure Following Trauma," *American Journal of Physiology*, Oct. 1, 1901) which I regret to have overlooked.

tie questioning. On account of the swelling of face and head it was impossible to determine whether or not there was fracture of the vault of the skull. The pupils were somewhat contracted but equal, reacting to light. There was slight left facial paresis and weakness of the left upper, and a lesser weakness of the left lower extremity. Speech, though somewhat indistinct, was not abolished. There was evidently no motor aphasia. The reflexes in the right upper extremity were slightly exaggerated and the right knee jerk could not be elicited, but there was some slight indication of an ankle clonus and a Babinski on the left side. Respiration and pulse were entirely regular and normal.

In view of the fact that there was no positive evidence of external injury to the skull nor of intracranial hemorrhage; in the absence of convulsive symptoms; and, furthermore, in view of the fact that twenty-four hours after the injury consciousness was not absolutely lost, I advised that operative interference be deferred, and that unless stupor were to increase and the paralysis to become more complete operative interference would not be necessary.

I saw the patient again on the succeeding days, and on the third day after the injury there was distinct improvement in the stupor, and although the patient was somnolent, she could be very easily aroused. The weakness of the extremities was less decided, the leg recovering so rapidly that there was some doubt as to whether it was much paralyzed. Sensation had never been disturbed and the patient soon regained control over the bladder. Speech was positively unaffected. Convalescence continued undisturbed, and ten days after admission the patient was, at her own request, discharged from the hospital and was practically certain to recover.

In view of the apparent severity of the initial injury, the enormous disfigurement of the face, there might have been reason to advise surgical interference, but in this case again the neurological evidence pointed to a tolerably small focal lesion. Nature is able to do more in the repair of such focal lesions, particularly if they are not near the cortical surface, than the surgeon can, and I am, therefore, firmly of the belief that in this case surgical nonintervention was the proper course to pursue. Had one been led by surgical appearances and by the mere probability of injury to the skull because of the character of the accident, a serious mistake might have been made and the patient's recovery would surely have been protracted if not considerably retarded.

Contrast with the preceding the case of a child of four years, who was brought into Mount Sinai Hospital on Sept. 29, 1905, ten minutes after the child had fallen out of a first-story window. The mother could not say which part of the body struck the ground first; she was certain, however, that the child was immediately unconscious and that there was bleeding from the left ear, mouth and nostrils. There were no twitches or vomiting. There was no involuntary micturition at this time and no deviation of the eyes. Exam-

nation by the house staff showed that the child was absolutely unconscious, groaning at times. There was a small punctured wound over the left parietal region. On account of the tremendous contusion of the scalp the physicians were not able to make out a depression over the parietal or any other region of the head. There was still some bleeding from the left ear, less from the nostrils, and a suspicion of fracture of the base. I was requested to see the child about seven hours after admission to the hospital and found that there was general edema of the left side of the face and head. The child was evidently able to move all its extremities though in a condition of deep stupor from which, however, it could be aroused. The pulse was slow, of poor quality and irregular in force and rhythm. The pupils were found to be small, regular, reacting sluggishly to light. Both eyes were turned inward; there was no subconjunctival hemorrhage. It was near midnight, the child was not wholly unconscious and the general condition was fair. I determined to await developments and saw the child again early the next morning. At this time I found it partly unconscious, responding intelligently to some requests. It moved freely in bed. There was a distinct left facial palsy. The palsy was peculiar in this one respect, that the lower branches failed to respond to the faradic current whereas the ocular branches did respond, from which I inferred (and the same inference I was able to make in another case of a similar character) that the facial palsy was not due, or at least not altogether due, to fracture of the base or to a central lesion, but was to be ascribed to the external contusion. At the margin of the edematous region of the scalp, a slight depression could be felt, and both the surgeon, Dr. Moschowitz, and myself at this time were quite certain that we could feel crepitation of the cranial bones in the left temporo-parietal region.

In this case, although the loss of consciousness was not complete and the general symptoms were not more marked than in some cases in which the diagnosis of simple concussion might have been made, I determined that the danger to the child would be far greater if the entire region were not explored surgically and lacerated brain tissue removed. The chief injury was evidently in the temporal region on the left side from which we could not have expected any paralytic symptoms, and in the stuporous condition of the child it was impossible to see whether or not there was speech disturbance. On the afternoon of the second day the operation was done, and from the surgeon's notes I quote that "a large horse-shoe shaped flap, about four inches in length, was outlined over the left side of the scalp corresponding in general to the squamous portion of the temporal bone. On incision of the skin and removal of the periosteum, a depression was seen with fractures running in various directions. Bone was removed over an area of 24 by 14 in. This exposed a large rent in the dura mater and showed the underlying brain tissue badly lacerated and mixed with blood. Portions of the brain coated out

between the ends of the fractured bone. The patient's condition grew alarming. The operation was hastily concluded by suturing the skin-flap and inserting an iodoform gauze packing after the hemorrhage had been carefully checked." In spite of our fears the child did well for some time after the operation. It became less somnolent, responded to questions by showing its tongue, etc.; there was no indication of any paralysis and there was no oozing of blood from the ear or nose. The child's hearing was not affected and it continued to do well until ten days after the operation when a sudden rise of temperature occurred to 104.2°; it became more somnolent, a fungus cerebri was developed, and some cerebrospinal fluid had continued to escape from the wound. The only inference was that infection had taken place, I believe almost unavoidably, during the various dressings, and on the thirteenth day after the initial symptom a second operation was undertaken for the purpose of bettering conditions if possible. The protruding mass was opened and disintegrated brain tissue was found which was pulsating slightly. There was no pus, but in the manipulation there was a sudden escape of considerable cerebrospinal fluid after which the mass collapsed and small tubes were inserted for drainage. Much to my surprise and that of the surgeons as well, the child continued to do fairly well until the twenty-first day when, against the advice of the physicians, the patient was removed to its home where it died a few days later, having lived twenty-six days after the initial injury. I may add that the culture of the fluid from the brain after the first operation revealed the presence of the staphylococcus albus.

The case was unusually instructive from several points of view. First of all, the retention of even partial consciousness in spite of the severity of the injury; the persistence of pupillary reaction; the entire absence of every form of paralysis; the tendency to convalescence for the first twelve days after the operation, and then the sudden exacerbation of all the symptoms, evidently due to secondary infection. Had it not been for the first operation, I fully believe that the child would not have survived as long as it did, for the brain tissue that was caught between the lacerated bones was bound to disintegrate and to become necrotic, and a general purulent meningo-encephalitis would have been the inevitable consequence within a few days.³ It is the difficulty of avoiding infection in these cases, or the difficulty of combating an infection which has taken place, that clips the surgeon's wings and baffles all our endeavors in cases such as these, and yet it is to be hoped that the day is not far off when infections within the cranial cavity will be treated with at least as much success as are at present those occurring within the abdomen.⁴

When drainage of the cranial cavity will be as well understood as is that of the pelvis and abdomen, and when surgeons will learn to handle the

brain as well as they have learned to handle the intestines, surgical statistics after brain injury will be far better than at present. Surgeons have not given as close study to the needs of the brain as they have to those of less dignified parts of the organism. In the mere matter of maintaining the natural heat of the brain, the surgeons are not nearly as careful as they are when they handle the gut. It would be well if they took Horsley's hint that during every operation on the brain, the natural heat of the brain must be maintained.

A question of distinct interest in connection with these injuries to the brain, is to determine the proper time for operation. If the skull has been most violently fractured, if there is a comminuted fracture of the skull accompanied by deep unconsciousness, by a slow and failing pulse and by irregular respiration, there seems to me to be every reason to advise surgical interference at as early a period as possible — within twenty-four or forty-eight hours. Valuable time should not be lost. But if the cerebral injury has not been so serious as to command immediate surgical intervention, I am of the opinion that if the symptoms point to a definite and, mind you, an accessible lesion in the brain the sooner the operation (if necessary, an exploratory one) is undertaken, the better. Moreover, I believe it is never too late to undertake such an operation providing the symptoms pointing to the existence of a definite focus are persistent and indubitable. The following is a case in point:

On May 24 of this year, I was asked to see Mr. A., a merchant forty-seven years of age. His family physician who had had him under observation for several months had correctly surmised that his symptoms were due to injuries which he had sustained. He was a man in good health, active in business and of bright intellect. His wife had never become pregnant, but his own personal history was absolutely negative. Luetic infection could positively be excluded. Three years ago while walking through a building that was in the process of erection, he struck his head against a beam. After this he had some headache, felt poorly, but paid no further attention to it, although the swelling of the scalp continued for several weeks. One and a half years ago he was waylaid at night on an Elevated railroad station and was struck with some heavy instrument on the head. He was stunned; was able, however, to get home and was not unconscious for an instant at any time thereafter. He suffered much from headaches, became somewhat disinclined to do work; the headaches became more intense at night than during the day, his sleep was disturbed, but for two months previous to my examination he had noticed hasty micturition and a tendency to somnolence during the day. There was an occasional aphonia, not an aphasia in any sense. He was able to read print and script. I was called to see the patient chiefly on account of the headaches and because he had noted considerable difficulty in writing. Good scholar as he was, he began to write imperfectly,

³ There was considerable injury to the scalp.

⁴ To avoid misunderstanding, I wish to express my admiration of the skill and devotion displayed by Dr. Moschowitz in the treatment of this little patient.

to spell badly, to omit words, and from Atlantic City he wrote a letter to his wife which might have been taken to be the letter of a man in the incipient stages of general paresis, — misspelling words, omitting others and exhibiting distinct tremulousness in the formation of his letters. At the examination, I noticed in addition to the facts already stated, that his speech was somewhat slow, reminding one a little of that of general paresis with the tendency to drowsiness and stupor, which was so great that while standing face to face and while he was being questioned, his eyes would close for an instant or two and then open, whereupon he would ask what the question was. The pupils were normal; the fundi appeared to be normal. There was a very slight right facial paresis, but there was no other form of paralytic disturbance. The wrist reflex was lively on both sides, and the deep reflexes of the lower extremities were increased. There was a distinct depression on the left side in the lower parietal region.

The partial agraphia, the slight disturbance of speech, the slight right facial paresis and the very insignificant depression on the left side of the head, all pointed to the existence of a small focal lesion, while the increasing tendency to somnolence, the hasty micturition and the intense headaches, indicated an increase of intracranial pressure, compression symptoms, if you will. Under these circumstances, although it was three years since the initial lesion, and although much doubt had been expressed as to the dependence of the symptoms upon the skull injury, I felt certain that there was either a small cyst or a localized cerebral pachymeningitis of traumatic origin. Five days later at my suggestion the patient was operated upon at Mount Sinai Hospital by Dr. Gerster. The scar was chosen as the site of the operation. There were marked adhesions of the dura to the skull; these were separated carefully; the exposed area was shown to be the leg center (by electrical stimulation); an aspirating needle was inserted to the depth of two inches which revealed the presence of an old hemorrhagic cyst which had been responsible for the symptoms; the dura was stitched and a celluloid plate introduced. The patient recovered well from the immediate effects of the operation.

After the operation there was absolute motor aphasia which I attributed altogether to the occurrence of post-operative hemorrhage. The patient recovered within the first three weeks, and then the recovery was uninterrupted and complete. I have seen the patient, a few weeks ago, five months after the operation; he is absolutely free from all headaches, the agraphia has disappeared and he is able to attend to his business as in former years.

In such cases as these, there would have been little use in discussing the question of concussion, confusion or compression. If there was anything of this sort in the beginning, there was a contusion of the skull with subsequent injury to the brain. This was followed in the course of time by a compression. How unimportant these

differentiations appear to be in view of the one and only significant fact that all the symptoms, slight as they were, pointed to a definite lesion. This lesion, moreover, was situated in an area in the brain that was accessible and was found to be within reach of the external injury. It was, therefore, incumbent upon us to advise operation in this case on purely neurological lines.

The result might have been a similar one in a medico-legal case in which I recently became interested. This patient was operated upon promptly and his more or less complete recovery was due, I believe, to the early intervention of the surgeon. This man was a builder, forty years of age, who had been passing out of an office building on Nov. 10, 1903, was struck on the left side of the skull by the head of a hammer which fell out of a ten-story window. He was stunned but did not lose consciousness at once. He asked for water, refusing whiskey which was offered him. He was taken in an ambulance to the House of Relief, where he was admitted and was subjected to surgical treatment. The patient could not recall reaching the hospital and does not remember anything from the time of the injury until the time he woke up from the operation. The hospital records state "compound depressed fracture of the skull with partial paralysis." The surgeons finding a depressed fracture and noting the paralysis, evidently resorted to trephining over the left parietal region in the vicinity of the leg center. He made a good recovery from his operation and was removed from the hospital thirteen days after the operation, at his own request, with the diagnosis "improved." Convalescence was undisturbed and the patient had been evidently improving ever since. At the present time he shows merely a slight weakness of the right upper and right lower extremity and increase of the reflexes in both the right arm and right leg. The man is unable, at the present time, to walk upon a high scaffolding and for that reason is suing for damages, and because he is incapacitated for work as a builder. With the medico-legal aspects of this case we, of course, have nothing to do. The fact cannot be gainsaid that if he had not been promptly trephined there might have been lasting paralysis of the arm and leg and possibly a chronic epilepsy. Whether trephining may be done to avoid epilepsy or whether it is entirely unnecessary to do it from this point of view, as Bergmann claims, is a question which we can hardly answer during this discussion, though I am willing to indicate that if a patient is brought in with a depressed fracture of the skull and his condition is otherwise such as to warrant operative interference the operation should be undertaken at once. The operation is practically a harmless one and it is far better to correct the depression than to run any chances in the matter of later epileptic disturbances.

From these personal experience, which I have selected somewhat at will from among a far larger number, I would lay stress upon the following points which I submit for discussion:

(1) If there is extensive injury to the skull, if par-

ticularly in the parieto-temporal region, whether it be fracture or fissure; if there is evidence of splintering of the inner table, or of the presence of a foreign body or of persisting intracranial hemorrhage, operative interference is warranted at the earliest possible moment. (X-ray examinations and lumbar puncture are valuable diagnostic aids.)

(2) In comminuted fracture of the skull the surgeon must decide whether or not the danger of infection is increased by surgical procedures. Surgical technique and surgical methods should be developed to such a degree that the brain and skull will be handled with as much skill as are the abdominal viscera.

(3) In all cases, but especially in those in which external injury cannot be taken to be the determining factor, the question of surgical interference must be decided on purely neurological lines.

(4) It is useless to continue the discussion of the differentiation between concussion, contusion and compression. It is much more important to decide whether the brain has or has not been tangibly injured; and if injured, whether the site of the injury is on or near the surface; in short, whether it is accessible or not. If inaccessible, simple trephining may be resorted to provided there are symptoms of increasing intracranial pressure which cannot be relieved by lumbar puncture or other simpler methods.

(5) Even if the injury is in an accessible region, it is best to adopt a conservative attitude and to determine whether we may trust to surgical skill rather than to the reparative powers of nature. Hemorrhages are often absorbed and many inflammatory processes recede more or less spontaneously.

(6) In determining the gravity of brain injury, disturbances of cardiac and respiratory action, of vesical and rectal control and the condition of consciousness are the most important symptoms. They are the manifestations of increasing intracranial pressure and of other serious injury. Recovery from coma, however slight, after twenty-four, forty-eight or seventy-two hours, is encouraging; deepening coma is of grave significance. The behavior of the pupillary reflexes is of no special value in deciding the question of operative interference.

(7) If the symptoms point to distinct focal lesion, although years may have elapsed since the initial injury, surgical measures must be adopted, providing only that the lesion be accessible.

(8) If the external injury points to one site and the symptoms to another, consider both; attack the site of external injury first but try to reach the other as well.

HEAD INJURIES.*

BY MORTON PRINCE, M.D., BOSTON.

I AM sorry that Dr. Sachs has eliminated from consideration fractures of the base. This distinction is entirely arbitrary, practically cannot

* Remarks in connection with a paper by Dr. Bernard Sachs, on "Serious Head Injuries." See p. 176.

be made, and, therefore, clinically is without value. Dr. Sachs seems to be unaware of the fact that, if we may draw conclusions from fatal cases, a localized fracture of the vault alone, at least in injuries sufficiently severe to implicate the brain, is rare.

I make this statement based on the study by Dr. Edwin W. Dwight of 146 autopsies, in which fractures of the skull were found. Dr. Dwight's paper, published in the Boston City Hospital Reports for 1894, is a very valuable one from a surgical point of view, and well worthy of study. It brings into relief many facts of importance. Out of 146 cases which came to autopsy, in only six cases was there a localized fissure of the vault alone. These, to be sure, were all fatal cases, and it is quite probable that in the non-fatal cases a localized fissure of the vault is more frequent, but, on the other hand, usually it is only through autopsies that we can determine the whole extent of the damage. The unreliability of the clinical signs is shown by the fact that in 31% of fractures of the middle fossa itself, no hemorrhage from the ear occurred.

The importance of this consideration is further brought out by the fact that in 29% of all cases, there was not only fracture of the vault extending into or through the middle fossa, but the fracture ruptured the branches of the meningeal artery, and death was believed to be due to cerebral compression.

We may say, therefore, that fractures of the vault, in the majority of cases, are fractures of the base, and we cannot, in the absence of the classical surgical signs, conclude that the fracture does not extend to the base, nor does it seem to me to be of any great consequence to make the distinction, inasmuch as it is the injury to the brain, and not to the skull, that does the harm.

Dr. Sachs has laid great emphasis upon the necessity of depending upon the neurological indications for determining the necessity of surgical interference. It seems to me that there is great danger here of creating and perpetuating a neurological tradition, just as there has been a surgical tradition as to the importance of separating fractures of the base from those of other parts of the skull.

We have been accustomed to hear, of late years, a good deal about the neurological indications in head injuries, the general implication, on the part of the neurologist, being that we can rely upon the neurological findings to determine both the character of the injury to the brain and its localization. These assumptions are usually meekly accepted by the surgeon as the dicta of a mysterious science. A good deal of this, I am afraid, has come to be little more than neurological cant. As a matter of fact, in a very large proportion of head injuries,—I mean injuries serious enough to implicate the brain,—technically speaking, there are no neurological signs of a special localizing character that give information regarding either the character or location of a lesion. I believe that anyone who has had the experience of a large general hospital, and thus has had an

opportunity to see a large number of cases, as many of us here have had, will find that this statement is borne out by his recorded experience. If he will look over the records of a large number of consecutive cases, he will find absence of localizing signs in the great majority.

I do not mean that there may not be general symptoms and other evidence that may enable us to form an opinion regarding the gravity and possible nature of the injury, but this evidence is not of that special neurological kind which may be technically called *neurological*. [Taking, for example, the cases I have seen within the space of a few weeks since Dr. Sachs' paper was read, nine in number, all carefully examined and noted, in only one were there so called neurological signs which indicated the seat or nature of the injury (whether hemorrhage, laceration, contusion, edema, etc.), and this one, a peculiar form of paraphasia with delirium, permitted only a doubtful localization. The neurological symptoms did not indicate the nature of the lesion. Seven of the cases were severe; six exhibited evidence of fracture of the base.]

In Dwight's collection "the question of paralysis was unfortunately raised in sixty cases" only. By this it appears to be meant that it was noted in only sixty whether or not paralysis was present. Of these, forty had none. (In seventeen, hemiplegia was found; in one, facial paralysis; in one, paresis of one arm, and in one, paralysis of the sphincters — a questionable diagnosis.) In other words, in two thirds of the fatal cases in which a record of the point was made there was no paralysis present. The proportion is probably higher than this, inasmuch as these statistics are based upon whether or not a symptom was recorded, and common experience shows that the absence of a symptom is much less likely to be recorded than its presence.

It must also be constantly kept in mind that even paralysis does not always indicate hemorrhage or laceration, but that it is sometimes due to edema, which may subside. I recall well, for instance, the case of a child which after a severe fall presented all the classical symptoms of meningeal hemorrhage. Operation was considered, but postponed, and, much to my surprise, in the course of twelve hours all the symptoms disappeared and a complete recovery was made. This could only be due to edema.

The greatest difficulty in determining the exact pathological lesion present and, therefore, the advisability of operation is met with in those cases that are unconscious from the beginning. When the accident does not result immediately in unconsciousness, or, if it does, when the unconsciousness is only temporary and then after a normal interval unconsciousness develops, the case is simple enough. Here the interval of normal consciousness is a plain indication, not only that the latest succeeding unconsciousness is due to a secondary hemorrhage, but that the brain tissue itself was not seriously bruised, lacerated or otherwise injured by the traumatism.

When, however, the injury is followed immediately by persistent unconsciousness, stupor or delirium, it is much more difficult, and often impossible to determine whether the coma and other cerebral symptoms are due to a hemorrhage or contusion or laceration or all three. To obtain data that will enable us to draw conclusions as to the exact anatomical conditions present in such cases, we are obliged to fall back upon the findings in autopsies. With this knowledge in hand, supplemented by the clinical findings and the nature of the accident, we may be able to form a fairly accurate idea of what has taken place within the skull.

The fallacy of drawing conclusions from autopsy findings, of course, is that they tell us only what has happened in fatal cases, which cannot be safely applied to the non-fatal cases. Still, as the difference must be only one of degree, the symptoms and the autopsy findings in fatal cases are instructive. Out of 138 fatal cases in Dwight's collection, in only 22 or 14% was there no laceration. Of course, in the other cases there was hemorrhage besides. This frequency of laceration explains the fact that in so many cases in which trephining is performed and a hemorrhage found and removed, a fatal result is not averted. There is so much laceration of the brain itself that the mere removal of a hemorrhage accomplishes little.

Plainly, the advisability of operation must depend upon the nature of the lesion within the skull. In deciding whether we have to deal with a hemorrhage or laceration or contusion of the brain or a combination of the three, and the extensiveness of the lesion (putting aside the classical and simple cases of meningeal hemorrhage) we must take into consideration four kinds of evidence:

First. The nature of the blow. Was the blow (meaning not to the person but to the skull) of a character which would be likely to shake and lacerate the brain, as well as rupture a vessel? A person may have a severe fall, and yet the head may not be struck severely, while the reverse may be the case. If a person should fall from a height and strike his head with violence, it would be almost a certainty that the brain would be lacerated; whereas, a blow from the fist or a slight fall from the street might only rupture an artery, without greatly bruising the brain.

Second. The general symptoms, such as coma, temperature, pulse, stertor, etc.

Third. The neurological indications.

Fourth. Surgical evidence of injury to the skull.

In many cases, the first class of evidence — the character of the blow to the head — will furnish most important evidence. All the evidence must be weighed and considered as a whole.

The larger one's experience, the more conservative, I think, one tends to become in advising operation. This is explained by the great frequency of laceration which under any good that might come from the removal of a hemorrhagic clot, as well as the difficulty in finding it.

In many cases it is impossible to decide whether we are dealing with pure hemorrhage or not; but, as with appendicitis, we shall often have to operate unnecessarily in many cases, that is, in cases which would have recovered without operation, or without doing good, in order to make certain of not letting a patient die for lack of operation. The fact I have already mentioned, that in 29% of Dwight's fatal cases, the fracture of the vault in extending to the base had ruptured the meningeal artery, and that death was believed to be due to compression from clot, must make us dread lest we should lose a life by neglecting to operate. And yet the conclusion that death might have been averted by removal of the clot, if it had been possible, in the 29%, is hardly tenable, considering the presence of laceration in 140 out of 146 cases.

INDICATIONS FOR OPERATION IN HEAD INJURIES.*

BY WILLIAM N. BULLARD, M.D., BOSTON.

In speaking of the indications for operation in head injuries only certain general lines of treatment can be laid down. There must be exceptions to the general rules in certain cases, to some of the rules in many cases. Each doubtful case must be considered by itself and acted upon as seems wisest when all the special circumstances have been duly weighed.

The following are the rules which I have found useful from my practice and experience in cases of fracture or suspected fracture of the skull.

Wherever we have absolute evidence of fracture by sight or touch our course is comparatively plain. It is in those cases in which we cannot be certain as to the existence of fracture, although the injury or condition is a serious one, that the greatest difficulty arises in determining our course.

We will first consider the cases in which we have absolute evidence of fracture by sight or touch.

Compound fracture of the outer surface of the cranium. I believe that operation in these cases in adults is always advisable, assuming that there are no serious contra-indications from the general condition of the patient, the condition of the heart or kidneys or injury or disease in other portions of the body. Hereafter, throughout this paper, I shall assume that such contra-indications are understood not to exist.

In compound fracture of the external surface of the cranium in adults, *operate*. Probably even in long linear fractures where there is no displacement or depression of bones, it is wiser to operate. The operation under proper conditions should not be serious and the risks which are run in the non-operated cases cannot at the present time be estimated. While probably most of such cases show no serious sequence, we never can be certain that epilepsy or some other serious consequence may not follow such an injury.

SIMPLE FRACTURE OF THE EXTERNAL SURFACE OF THE SKULL.

In adults it is safer to operate in all cases where there is clear external evidence of fracture. In children it is sometimes permissible not to operate in cases of fracture of this kind where no symptoms exist.

Depressed fractures. In adults depressions rarely or never occur without fractures. All depressed fractures should be operated upon.

CASES OF HEAD INJURY WHERE FRACTURE IS SUSPECTED OR MAY EXIST.

Cases in which the question of operation is determined by the existence of symptoms other than the existence of the fracture itself.

There are certain symptoms or groups of symptoms which when they accompany or follow serious head injury have great weight in determining the question of operation.

Operate (a) in all cases where symptoms of middle meningeal hemorrhage exist. We should as a rule operate in any case where unconsciousness comes on after an interval of consciousness following injury to the head.

Operate (b) in adults whenever the unconsciousness after a severe head injury lasts more than twelve hours and where it seems clear that the unconsciousness is due to the injury and not to alcohol or other causes or complications. This rule is not universal. It is true that a certain number of these cases recover without operation and even may have no further symptoms, but operation is usually the safest plan.

(c) As a rule it is wise to operate where persistent unilateral convulsions follow injury to the head in an adult, provided that such convulsions have never occurred previous to the injury and that no other cause for them, such as uremia, exists.

(d) When cerebral or meningeal paralysis occurs immediately following a severe injury to the head, the question of operation often arises. Hemiplegia or monoplegia under such circumstances do not absolutely indicate operation. They may be due to hemorrhage or other injuries in parts of the brain which are out of reach. This condition may have been the cause of the fall or injury and not the result.

(e) Inequality of the pupils occurring immediately or shortly after injury is indication in favor of operation.

(f) Temperature: Immediate and persistent rise of temperature (not otherwise accounted for) occurring after severe head injury suggests contusion or laceration of the brain. Rise of temperature within twenty-four to seventy-two hours after injury, especially if the patient is unconscious, suggests secondary encephalitis or inflammation of the brain.

(g) Pulse: Slow pulse suggests compression, hence, with other symptoms, is an indication for operation. Rapidity of the pulse in itself does not contra-indicate operation. Weakness of the pulse may be a contra-indication.

The third class of cases to be considered is that

* Read in connection with a paper by Dr. Bernard Sachs, in "Serious Head Injuries," p. 176.

in which the patient is found unconscious or for any other reason unable to give an account of himself, and trauma must be considered, although the evidence from history or signs is not definite. In these cases operation is only justifiable or advisable when all other ordinary causes for the condition are excluded.

We must carefully exclude alcoholic edema, uremia, diabetic coma. Non-traumatic apoplexy is a common cause of such conditions and they may be produced in tumor of the brain or in various forms of meningitis. Hemiplegia or monoplegia in these cases is not in itself an indication for operation.

Clinical Department.

BRAIN INJURIES.

1. GUNSHOT WOUND INVOLVING BOTH OCCIPITAL LOBES: STUDY OF VISUAL FIELDS.

2. FRACTURE OF SKULL: INJURY TO FRONTAL LOBE.*

BY HENRY C. BALDWIN, M.D., BOSTON.

W. C. S. Thirty-four years. Service of Dr. James G. Mumford, Massachusetts General Hospital.

July 24, 1905, the patient was brought to the hospital with a history of having been shot five hours previous by the accidental discharge of a 32 caliber rifle. The bullet entered at the lower part of the right occipital region, and the direction of the bullet was diagonally upward.

I was asked to see the patient in consultation by Dr. Mumford. The patient was conscious, and had been ever since the accident. There were no paralyses of the face, arms and legs. The reflexes were all normal. The pulse was not slow. The only symptom that the patient had was total blindness. The pupils were widely dilated, and did not react at all. The diagnosis was made of injury to the visual centers in both occipital lobes. An X-ray showed that part of the bullet was lodged near the entrance of the wound on the right side, and that part of the bullet was in the occipital lobe on the left side. The point of entrance

was very small, and it was recommended that large openings should be made over both occipital lobes to give good drainage.

Free openings were made by Dr. Mumford on both sides. On opening the skull on the right side, disorganized brain substance and considerable blood oozed out, and the finger of the operator went into a cavity. There was a hole through the falx cerebri, and a piece of bone was extracted from the left occipital lobe, which had been carried through the falx from the point of entrance. The piece of bullet located in the left occipital lobe was not found, and it was not deemed wise to risk doing any damage by searching for it. A recent X-ray shows a piece of bullet still remaining in the left occipital lobe.

The patient was totally blind the next day, but there were no other symptoms. Three days later the patient began to see a little, and his pupils became smaller and responded to light. There was no rise of temperature, and the patient had no symptom whatever except his impaired vision. Before he left the hospital, an examination by Dr. Tracy Eastman was made of his field of vision and of the condition of his fundi. The field of vision was absent on the left side; there was about a quarter field of vision on the right side, the right eye having a larger field than the left, as shown by the diagram. The vision was 20-20 in the quadrant of each eye, and the fundi were normal. In this case the total blindness at first was due to destruction of the visual center in the right occipital lobe, and to injury to and hemorrhage into the visual center of the left occipital lobe. Undoubtedly, the free openings that were made over both occipital lobes were largely instrumental in preventing sepsis, and the free drainage afforded aided the recovery of the injured center on the left side.

The patient reported to me Nov. 16, 1905. His field of vision had increased a little, as shown by the diagram. Dr. Alex. Quackenbos stated that the vision and fundus were normal. The patient told me that he had been out shooting and had been able to bring back partridges and squirrels.

The field of vision was taken by Dr. Robert C. Loring on Dec. 16, 1905, and the diagram shows an increase in the field of vision. The vision and fundi are normal.

FIG. 1. Visual field, Aug. 17, 1905.

* Read at a meeting of the Society of Neurology and Psychiatry, Nov. 10, 1905.

Cases of gunshot wounds causing injury to both occipital lobes are rare. In the medical and surgical history of the Civil War, exclusive of cases that were fatal on the field, there were reported 4,350 cases of gunshot injuries of the cranium. Of these cases 2,514 died. There were 559 cases of penetrating and perforating wounds of the skull, 458 of which died. In looking over 119 cases that were given in detail I can

South Africa," Makins reports three cases of injury to the left occipital lobe and two cases of injury to both occipital lobes due to gunshot wounds. In one case of injury to the left occipital lobe, no mention is made of the field of vision, but in the other two cases there was hemianopsia. In the two cases reported of injury to both occipital lobes, the fields of vision were affected in both eyes.

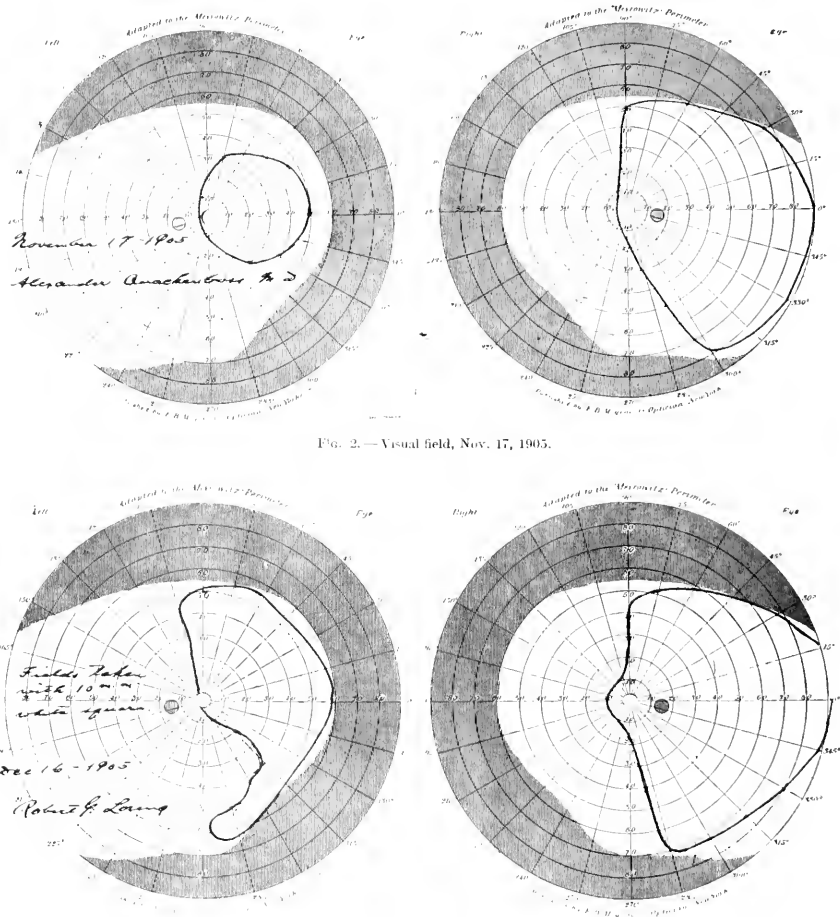

FIG. 2.—Visual field, Nov. 17, 1905.

FIG. 3.—Visual field, Dec. 16, 1905.

find no case of injury to the occipital lobes reported. It is interesting to note that there are but 1,190 gunshot wounds to the eye reported, and that only 63 of these cases lost the sight of both eyes.

In his book entitled "Surgical Experiences in

MASSACHUSETTS GENERAL HOSPITAL.—SERVICE OF
DR. W. M. CONANT.

C. E. II. Fifty-five. Man was struck and knocked down by an electric car, June 16, 1905. When brought to hospital was noisy, restless and apparently drunk. There was no disturbance of pupils or reflexes. There

was fracture of the left clavicle; no fracture of the skull made out. There was no bleeding from ears, mouth or nose.

The patient had nothing remarkable in the way of symptoms.

July 1, I was asked to see him in consultation with Dr. Conant, as a matter of routine and to express an opinion as to the advisability of his leaving the hospital. He had a normal temperature, his reflexes were all normal, and there was nothing remarkable about the pupils. The patient answered questions readily and correctly. There was an area of discoloration over the forehead running down into the right eye, which gave evidence of the patient's having received a very severe blow. The mental condition, though not confused, was dull, and the man seemed apathetic and slow in comprehending and answering. The diagnosis was "the results of concussion and alcoholism," and further observation was advised.

The patient became duller five days later, and died a week later after having run a septic temperature for a few days.

Before the autopsy I stated to the House Officer that they would find a fracture running through the frontal bone; that one of the anterior lobes of the brain would be found disorganized, and that the patient died from sepsis through the infection of this disorganized lobe, the entrance of the infection being through the nose. The picture shows the condition found.

These cases where the anterior lobe is seriously injured by direct violence have not been very common in my experience. Both patients had no symptoms that were localizing or that indicated mental disturbance. Their dullness and slowness of mentality were all the symptoms that indicated any brain trouble. In both instances it has seemed to me that, if the condition had been recognized, or rather suspected, operative treatment might have been effectual. Where such a condition was suspected, or where in a head case with a history of direct violence to the front of the head the patient began to run a temperature, it seems to me that it would be justifiable to make an exploratory incision to ascertain if there were a fracture of the skull. If such a fracture were found, an opening into the skull to afford free drainage would seem to give the patient a chance. Such an incision could be made in the hair line, the flap being turned down to give a view of the forehead. An opening through the skull on the side to avoid the frontal sinus would give good drainage to the anterior lobe.

A CASE OF ADIPOSIS DOLOROSA.

BY E. W. TAYLOR, M.D., AND R. L. LEE, M.D.
From the Neurological Service, Long Island Hospital, Boston.

THE rapidly increasing reports of cases of *adiposis dolorosa* have not shaken Dercum's original claim, that the condition merits the distinction of being regarded as a distinct disease, separable from simple adiposity on the one hand and myxedema on the other. The affection commonly known abroad, as well as in the United States, as Dercum's disease has taken a perfectly definite place among the easily recognizable disturbances of nutrition, in spite of the fact that the final etiology remains obscure, and a specific form of treatment has not yet been found. The following case is reported as a somewhat typical instance of painful obesity, following general alcoholic poisoning.

Margaret A., aged thirty-nine, born in England, married, occupation, housework; entered the Long Island Hospital Jan. 11, 1902.

Father is living in England; mother died at forty-seven of phthisis; of two brothers and seven sisters, five died in infancy, cause not known; two sisters and one brother living and well. Most of mother's family died of phthisis. None of the family ever had a disease similar to the disease of patient.

She had measles and pertussis when a child. Other wise healthy. Menstruated at fourteen; menstruation has never been troublesome. Married at seventeen, and has had five children, three of whom are dead, one died of convulsions, one of brain trouble, and one of unknown cause. She has had two miscarriages, which occurred between the births of living children. Pharyngitis seventeen years ago. She says she began to have rheumatism seven to nine years ago, when it came after exposure to wet and cold, and was accompanied with swelling of feet, pain, tenderness and numbness. These symptoms were confined to the feet and legs and lasted for from ten to twelve weeks, during which time she could walk only with the aid of

FIG. 4.—Showing injury with softening to frontal and temporal lobes.

This is the second case that I have seen of this kind. The first case was a man who was riding on a bicycle and ran into an electric car. He was not unconscious, and presented no symptoms for over two weeks, when he ran a temperature and died of sepsis. The right anterior lobe was even more disorganized than was the case in this instance.

crutches. She had several attacks after this which usually came in the winter and after exposure.
 * Habits: About twelve years ago patient began to take whiskey to excess. Since this time up to entrance she was intoxicated for four weeks at a time and then again went a year without drinking. For five months before entrance she was intoxicated much of the time. She denies venereal disease.

Eight weeks before entrance upon awakening in the morning patient could not get out of bed owing to pain in the legs when weight was put upon them. When in bed she was free from pain. She complained of weakness in her knees which in a few days was present in her hands associated with pain and soreness. At this time she would drop anything placed in her hands. The pain was severe and described as shooting down the arms to the fingers and similarly down the backs of the legs to the toes. For a month previous to entrance she vomited two or three times every day, generally after ingestion of food.

Physical examination at time of entrance showed nothing abnormal except general tenderness over the entire body but especially over the nerve trunks; pain on motion and marked ataxia of arms and legs. Knee jerks and plantar reflexes were absent; no clonus. Temperature was elevated. Urine negative. Examination of blood showed hemoglobin 70 per cent; reds, 5,800,000; whites, 18,200. Her mental state attracted no special attention.

After entrance the condition of the patient showed no improvement until the latter part of February, when the paralysis and anesthesia in the hands were less marked and she complained less of pain.

On March 23, 1902, although the patient had apparently been familiar with her surroundings, as she expressed it, she "came to herself." She remembered nothing of her stay in the hospital to this date and did not remember having seen the visiting physician before. From this time to the last of April she steadily improved although she still complained of pain and swelling of the legs; she was, however, able to sit up in a chair. Her legs continued to swell and during the fall of 1902 it was noticed that she was gradually increasing in size over the entire body which seemed to be more marked when she was up, no doubt due to natural physical causes.

A physical examination Nov. 20, 1902, showed that the patient was unable to stand; that the knee jerks were still absent and that there was an increase in general size, but particularly of the lower extremities. The legs were larger every way than formerly; just above the knees there were large tabs of tissue. The arms had also increased in size and on the upper arms behind were large, flabby, lipomatous masses. The breasts and abdomen were not at that time increased in size. Measurements:

| | |
|--------------------------------------|------------|
| Left thigh (5 inches above patella), | 23 inches. |
| Right thigh, " " " " | 22½ " |
| Right calf, | 17½ " |
| Left calf, | 17 " |
| Left ankle, | 11½ " |
| Right ankle, | 12 " |
| Left upper arm (greatest circum.), | 17 " |
| Right upper arm, " " | 16¾ " |
| Left forearm (3 in. below elbow) | 11 " |
| Right forearm, " " " " | 11½ " |

Her urine varied in amount from day to day (980 to 3,150 cc.). She had during the fall several gastric upsets and severe attacks of headache; also pain in arms, fingers and legs.

Measurements taken Jan. 8, 1903:

| | |
|--------------|-------------|
| Right thigh, | 23½ inches. |
| Left thigh, | 24½ " |

| | |
|-------------|-------------|
| Right calf, | 18½ inches. |
| Left calf, | 18½ " |
| Right arm, | 11½ " |
| Left arm, | 11½ " |

Physical examination at this time showed movements of legs fairly free except as restricted by pain. Deep pressure, irrespective of the nerve trunks, was painful. Tactile sensation was normal over legs. Plantar reflexes absent.

Showing fatty pads on arms and back, and fatty nodules, especially marked on the thigh.

During the spring of 1903 she had paroxysmal attacks of pain occurring every two or three weeks and lasting for a few days, located chiefly in the legs.

Measurements taken July, 1903, showed:

| | |
|----------------------|------------|
| Right leg (at knee), | 22 inches. |
| Left leg, | 21 " |
| Right calf, | 19½ " |
| Left calf, | 18½ " |

On July 31, 1903, a thrombus of a superficial vein of the arm was diagnosed. During the summer the patient gained considerably in weight; the pain seemed to be increasing and continued sporadically throughout the whole of the fall and winter.

During the spring of 1904 the patient continued to gain in weight; the pain became less severe and came at less frequent intervals. Since Feb. 20, 1904, she has been able to walk at times with comparatively little discomfort.

Sept. 1, 1904. She now complains of pain which is of the "pins and needles" variety and which occurs in hands, arms, feet and legs. The pain is paroxysmal, on some days the patient being entirely free from it and on others requiring the use of morphia. The pain in the hands is accompanied by a fine tremor of the hands and fingers. Menstruation apparently has no

relation to the pains. Headache is a very troublesome symptom; this is much better after the menstrual period which occurs regularly every four weeks. Patient says she never feels warm enough to sweat and her skin is always dry. Hematemesis or hemoptysis have never been present, but she says that scarcely a day passes without a slight epistaxis. She has not suffered from bronchitis or dyspnea. She had an eruption on the body several years ago, "similar to measles." (The records of the hospital give no account of this.)

About the latter part of August, 1904, a red, swollen, painful area about the size of a half dollar appeared on the anterior aspect of the left lower leg just above the ankle. No fluctuation was ever obtained and the redness and swelling subsided in about a week under treatment with flaxseed poultices. A similar area appeared soon after on the outer aspect of the other ankle and later one appeared on the abdomen. Both subsided in a few days. She has never had any abnormal sensations of heat or cold.

During the first part of the time the patient was in the hospital a weight chart was not kept but she says that the first time she was able to be weighed, which was in the spring of 1902, she weighed 148 pounds. She now weighs, Aug. 30, 1904, 260 pounds. There has been a progressive gain in weight during the past year. Treatment has consisted of alternate treatment with potassium iodide and thyroid extract, as much as 5 gr. t. i. d., being given of the latter for a considerable period of time but apparently without effect.

Nov. 14, 1904. Since August there appeared a red, swollen area in the left axilla similar to areas previously described and which passed away in a similar manner. Patient now makes no complaints except of pain in and on pressure over areas of fat, and of dizziness. Her appetite is fair. She has no trouble with her sight, hearing, taste, smell or speech. Her sensibility to touch is normal. There is no pain on pressure over any definite nerves. Her grip is strong and equal on both sides. Pulse is rapid (130), of fair volume and tension. Her heart area cannot be satisfactorily marked out on account of her obesity; the heart sounds are faint but no murmurs are heard. There is no edema. Her general color is good; the face is generally flushed about the cheeks. Knee jerks are slight but equal on both sides. Her hair is plentiful and moist. She is in good general spirits much of the time and gets about the ward with the aid of a chair which she pushes in front of her. She now weighs 273 pounds. Measurements taken at this time are as follows:

| | |
|--------------------------------------|----------------|
| Left thigh (5 inches above patella), | 27 1/2 inches. |
| Right thigh, | 26 1/2 " |
| Right calf ("greatest circum."), | 20 " |
| Left calf, | 20 " |
| Left ankle, | 11 1/2 " |
| Right ankle, | 11 1/2 " |
| Left upper arm (greatest circum.), | 20 " |
| Right upper arm, " | 21 " |
| Left forearm (3 inches below elbow), | 13 " |
| Right forearm " | 13 " |

The fat bears no relation to muscles but in addition to its general distribution it exists in large flabby masses which hang from under her arms and from the scapula, thighs and calves. The abdominal fat hangs in a heavy, apron-like fold on the thighs and the breasts are large and pendulous. The fat of the lower legs hangs in a roll over the ankles, is extremely tender to the touch, firm, and has a lobulated contour feeling in many places similar to a varicocele but considerably harder.

Nov. 26, 1904. There is no indication left of the former neuritis; nerve trunks are not painful; there is

no atrophy of the small, hand muscles in which Faradic reaction is easily obtainable; the skin is normal in appearance. To-day the fat of the arms, irrespective of nerve trunks, is exceedingly painful whereas other portions of the body are not. According to the patient's statement the painful areas vary from time to time for no apparent reason. Sensibility and motility, except as interfered with mechanically by the fat, remain normal.

The year which has elapsed since the last notes were made has seen no definite change in the physical condition of the patient. She is enormously fat as already described and pain is frequently easily excited by pressure over the fatty masses. On the whole she has improved somewhat physically and gets about with greater ease than formerly although naturally still with great difficulty. Her mental condition is of much interest. There is no sign whatever of dementia, but the variety of her moods may certainly be regarded as pathological. At times she is effusive in her appreciation of what has been done for her and at others she becomes morose and disagreeable in manner with an ability to find fault, which is wholly unnatural and for which there is absolutely no cause. In her doleful moods she is unable to account for her moroseness and altered feelings. She admits that she has received nothing but kindness at the hands of her attendants and regrets her ill temper which she says she is totally unable to either explain or control. Her general manner on these not infrequent occasions is that of a sulky and fault-finding child. There is no evidence to show that this change of temperament was habitual with her before her illness.

The points of special interest in this case are, the onset directly following and apparently in association with an alcoholic neuritis; the diffuse distribution and characteristic pain of the fatty deposits, and the mental symptoms which immediately preceded the development of the fat and have persisted in different form since.

There can be no doubt that when the patient entered the hospital in 1902, she was suffering from alcoholic excess, which manifested itself as a generalized neuritis, and which so far affected her mental state that up to a certain date she remembered nothing of previous events. There was at no time a definite delirium, and the failure of memory afterwards noted was not conspicuous during the earlier period of her illness. She was at this time a woman of ordinary size. As the neuritis improved, a gradually increasing weight made itself manifest, as indicated in the foregoing history, characterized by diffuse deposits of fat, painful on pressure and manipulation. The character of these fatty masses corresponds closely to Dereum's description, — lobulation, "worm-like" feel, with extreme sensitiveness at times. It is, however, worthy of special remark that the sensitiveness of the fatty deposits varies markedly from day to day and week to week, and is not to be explained by the assumption of a persistence of the neuritic process, for which she first sought relief. There is now no evidence that special nerve trunks are involved, and the pain appears wholly limited to the fat. Discrete fatty tumors are nowhere in evidence, nor is an ordinary adiposity to be considered in view of the accompanying symptom of pain. The mental condi-

tion of the patient has been described. In view of other reported cases, its association with the general process may be assumed as probable. It is, in any event, certainly abnormal, and is not unlike the condition of a patient described by Vitaut.¹

Since Dercum's first description of the disease in 1888, and later under the name of "adiposis dolorosa," in 1892, much attention has been paid to the subject, and the list of references no longer permits us to regard the affection as among the rarities. Several facts are noticeable in this connection, that Dercum has been given full credit by foreign and American writers alike for his pioneer work, that extremely little has been added to his first descriptions which, although now nearly fifteen years old, may still be read as a wholly adequate description of the affection; and finally that the attempt to deprive the symptom-complex of its claim to independence has signally failed.

Vitaut² has discussed in comprehensive form the existing opinion regarding the affection up to the time his paper was written. The four cardinal symptoms, of lipomatous tumors, pain, asthenia and psychic disturbances, are recognized. Accessory symptoms are motor disorders, sensory and special sense disturbances, and particularly disorders of the sympathetic system. He distinguishes these types of the affection, as nodular, diffusely localized, segmental and diffusely generalized. The etiological factors are considered to be neurotic heredity, alcoholism and traumatism. Anatomically these stages may be recognized in the development of the lipomatous tumors, edema and embryonic mucoid tissue, tissue, in process of organization and fat, and, finally, fat and sclerosis. The mechanism of the production of the tumors is regarded as certainly through the nervous system, and the cause which puts this mechanism into play is very probably an intoxication of thyroid origin, as indicated by clinical analogy, lesions of the thyroid found at autopsy, and the results of treatment.

With these general conclusions there will, no doubt, be considerable divergence of opinion. The possibility of distinguishing three types is questionable, although on purely clinical grounds such an attempt may be useful. It also helps very little, to place hereditary predisposition and trauma in the category of etiological factors, and alcohol, although probably operative in our case and in several others reported, must certainly be given a place of merely relative importance. Furthermore, to say that the mechanism of the production of the tumors is surely nervous, does not help toward the elucidation of the real question at issue. That the thyroid gland has a share in the process seems highly probable, but far from proved. The treatment by thyroid preparations has been occasionally beneficial, but by no means universally so. In our case its effect was altogether doubtful. In general, the enthusiasm expressed by Vitaut for the thy-

roid treatment will hardly be received with unqualified assent.

An admirable review of the whole subject has recently been made by Weiss,³ who expresses himself conservatively regarding the relation of the thyroid gland to the disease and to its treatment. He regards the treatment as uncertain, and the probability merely established that the thyroid gland has a share in the production of the affection.

The disease still awaits a satisfactory explanation, and no doubt its actual etiology will remain obscure, until we have progressed much further in our understanding of the body metabolism.

Reports of Societies.

THE BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

HELD ITS REGULAR MEETING, NOV. 16, 1905, WITH THE PRESIDENT, DR. MORTON PRINCE, IN THE CHAIR. W. E. PAUL, M.D., SECRETARY.

DR. BALDWIN reported two cases of skull injury.¹

A CASE OF CONTINUOUS AMNESIA.

DR. MORTON PRINCE showed a case of continuous amnesia, resembling, in certain respects, Korsakoff's psychosis. The loss of memory had followed an illness, characterized by delirium and paraplegia, which had occurred about one year previously, but the exact nature of this illness could not be determined from the history. It was possibly a multiple neuritis, although the sphincters were involved. After coming out of the delirium, there was *retrograde* amnesia for a period of a whole year preceding the attack. During this time he had been editor of a newspaper, but the patient remembered absolutely nothing of what he had done during that year, although he had been married at some time during this period. Since the paralytic attack, he had been affected with *continuous* amnesia; that is to say, the patient forgets everything as fast as he experiences it. For instance, in a minute or two after entering a room, he forgets how he got there, and similarly, after being examined, forgets everything that has been done to him. He loses his memory for persons, places, etc., in the same way, yet his reasoning powers are acute. There is no loss of logical capacity, nor, as far as one can tell, of memory of the events of his life preceding and up to the beginning of the retrograde amnesia when he entered upon his editorial duties. The events of this part of his life he recites apparently with normal ease, as he also can repeat passages from books which he learned at a date preceding the amnesic period. [The patient here recited a passage from "Paradise Lost."]

The case differs from Korsakoff's psychosis in that no falsification of memory can be detected. The association of continuous amnesia with retention of a normal logical power of reasoning and clearness of thought, without delusions, falsification of memory, or apparently impaired reasoning power is a striking feature of the case.

A complete account of the case is reserved for publication.

DR. SACHS, of New York, read a paper on

SERIOUS SKULL INJURIES AND THE INDICATIONS FOR OPERATIVE TREATMENT.²

DISCUSSION.

DR. J. C. WARREN. It is encouraging to the surgeon to see a specialist of Dr. Sachs' standing interested himself in this subject as it seems to display a more hopeful prognosis for traumatic brain lesions. When cerebral surgery was first expected under hopes were raised and a period of reaction has followed. Now that renewed attention is being given to the subject we may hope that a more accurate pathology may be worked out and more definite rules established for the surgeon's guidance.

A satisfactory diagnosis can be made in these cases by the painstaking and precise work which only a specialist can give the task, the surgeon's role being, in certainly a large number of cases, simply that of the artisan ordered to do a prescribed piece of work.

In view of the dreadful possibility of epilepsy we are justified in persisting in the attempt to find out a way of operative relief if such be possible. In even the worst cases surgical help is sometimes of benefit. What the brain can stand in the way of injury was shown in the famous crowbar case. Free drainage seemed to have been the secret of success on that occasion.

We should not hesitate therefore, as surgeons, to hope for a good result sometimes, even in the most desperate cases and there is little doubt that a new study of the conditions predisposing to traumatic epilepsy may lead up to more encouraging surgery in the future.

DR. F. B. LA SALLE said that he felt that most surgeons would agree with Dr. Sachs in his conservative treatment in the first two cases reported in his most interesting communication. In regard to operating on the third case he could not feel that operation was made necessary by the fact that lacerated brain lay between the edges of the fissure in the skull; he had seen so many cases get well without harm from the necrosis of a lacerated brain that he no longer feared it. If the case was aseptic the necrotic tissue was absorbed and there was no abscess formation or any other harm resulting from it. In many cases of trephining more or less of the lacerated brain, either crushed against the edges of the bone or otherwise injured, was sewn up under the flap, and in his experience its presence had never resulted in harm if the case were aseptic. He thought it hardly fair to take the surgeons to task because less progressive work was being done in the field of cerebral than in that of abdominal surgery. In abdominal surgery we were dealing with the tissues which we could handle, cut, stitch and manipulate with safety, and with excellent results to our patients. In the surgery of the brain we were dealing with an infinitely complicated and important system of cells and fibers, the substance of which was soft and gelatinous, and incapable of intelligent manipulation. Until we had some different tissue to work in, or some different instruments to work with, the surgery of the brain would never be brilliant. The results of manipulative efforts upon the brain itself were apt to result in paralysis, worse sometimes than those which it was attempted to cure. It is an interesting fact that Cushing, who in this country is at present doing the most to broaden the field of cerebral surgery, is devoting himself not to the brain itself but to skillful operative treatment of the calvarium and dura. He endeavors to relieve pressure and so make life endurable, in cases of tumor of the brain, the majority of which he recognizes are incapable of removal. To the surgery of the skull and membranes, and therefore indirectly of the brain, he has given a new impetus in this country. Surgeons as well as neurologists, perhaps even more than some neurologists, are ready to attempt the relief of patients with cerebral lesions which give any promise of operative relief, and all conscientious surgeons endeavor to avail themselves of all modern improvements in technique, but no matter how great their interest or enthusiasm the field itself of cerebral surgery never can be wide or afford such satisfactory results as that of surgery of other portions of the body. It did not seem to me that the surgeons should be reproached for a state of things which was inherent in the nature of the subject, or blamed for not attempting the impossible.

DR. J. W. COURTNEY. I must confess that I am about as unenthusiastic over surgical intervention in recent cranio-cerebral traumas as any one could well be. For my own guidance in such cases I have formulated a very simple set of rules. If there be an obvious depressed fracture of the skull or other exter-

¹ See p. 185.

² See p. 170.

nal injury which may cause cerebral complications, I consider it a matter of surgical common sense to deal with them operatively at once. So far the skull proper and its coverings are important; but to spend any more time on this aspect of a given case is, to my mind, injudicious. Now, if there is a reasonable certainty that we are dealing with a practically uncomplicated middle meningeal hemorrhage it is likewise a matter of common sense to invade the skull and remove it. When we go beyond this in surgical procedure we are getting into very deep water.

Every one conversant with such matters knows that when the cranium and its contents have been exposed to violence, the end results are by no means confined to the point of actual contact. A traumatism may, for example, cause a supradural hemorrhage at the point at which it has expended itself with maximum intensity, and at the same time produce not only laceration, but a generalized contusion throughout the brain, which in itself is quite sufficient to produce death. In such a case we may remove the supradural clot and yet be totally unable to save life by reason of the other factors present in the case.

The trouble is that in a given case we get our minds fixed upon the most salient features and overlook complications which, of necessity, portend a fatal issue. It is doubtless of great importance to examine every case of head injury with the utmost thoroughness of which the neurologist is capable, and yet the sad fact remains that neurological indications are most untrustworthy. I have long since ceased to regard the condition of the pupils and of the reflexes as of any special importance. Even a hemiplegia coming on late in a case is extremely misleading as a diagnostic criterion. I do not regard the temperature as of a great deal of importance, and I find, on the whole, that it follows a pretty definite course in the various forms of recent brain traumatism. At the outset it is subnormal, as would naturally be expected, from shock. If the case is one of uncomplicated cerebral contusion I look for a range between subnormal and 101° . If hemorrhage is the sole factor in the case, I find it remains very near the normal mark, but if there is any degree of laceration I look for a steady upward trend almost from the beginning.

Now, to my mind, any result of recent traumatism to the cranium outside of depressed fracture or some wounds which may give access to germs, and any intracranial condition outside of an uncomplicated superficial clot, had better be left to the mercy of nature. To interfere in any other condition is, in my belief, equivalent to adding insult to injury.

I would like to call attention to the fact that in a great many cases of cranio-cerebral traumatism, the cerebral aspect of the case is not the only one, and that the neurologist and surgeon are apt, in their zeal, to overlook injuries elsewhere in the body which, of themselves, are quite capable of producing death. As to surgical technique, I must say that I am thoroughly satisfied with the present conditions as they obtain at the Boston City Hospital. If an operation is done with a maximum of celerity and a minimum loss of blood it is as good a combination as we can hope to secure.

In conclusion, I would like to quote from an article of mine on traumatic cerebral edema, written in 1899, in which I said the following: "Our knowledge of cerebral localization and function has been derived in part from experiment and in part from induction based upon the pathological findings in cases of brain neoplasms whose clinical expression has been accurately observed. In the majority of such cases the march of symptoms is slow and the portions of the brain, outside

of those immediately concerned in the growth, healthy. In animal experimentation, moreover, where certain portions of the cortex have been successfully removed, this has been done piecemeal, and the remaining healthy portions of the brain not traumatized. In these two facts lies the secret of the limitations of cerebral surgery. In the removal of neoplasms the most brilliant successes have always attended those cases where limited regions of the cortex and its underlying tissue only were involved. In the surgery of cerebral traumatism the most successful results have been obtained when the conditions underlying the immediate injury to the skull have most closely simulated those of a circumscribed cortical neoplasm, namely, uncomplicated middle meningeal hemorrhage. Upon this point there is a singular unanimity of opinion, even among the most rabid advocates of the trephine. Roberts, after comparing trephining to amputation of the metacarpal bone, descends to this bald statement of fact: 'Hence operation is contra-indicated in cases of intracranial bleeding that do not present the symptoms which are believed to be produced by accumulation of blood in either the cavity of the arachnoid or the space between the skull and dura mater.'

"We may invade the pleural and peritoneal cavities with impunity, but in the cranium we are thus far met by insurmountable barriers. The outgoing century has done much toward the advancement of surgical science, but in the field of nervous surgery alone there is much for the coming century yet to do."

Dr. P. C. KNAPP: I had hoped to present a patient whom Dr. Lothrop had operated on over five years ago, removing an enormous extradural clot over an inch and a half thick covering nearly the whole of the left cerebral hemisphere. The hemorrhage came from one of the veins emptying into the longitudinal sinus. A Babinski reflex was present within six hours after the accident and had disappeared within ten hours after the clot had been removed. The man made a perfect recovery, but later developed mitral disease.

I cannot agree with Dr. Courtney that only extradural hemorrhages should be operated upon. In every case of meningeal hemorrhage where there are sufficient symptoms to warrant even a strong suspicion of the condition, an exploratory trephining should be undertaken whether the hemorrhage be extradural or intradural. It is, of course, sometimes difficult to determine whether the hemorrhage is extracerebral or intracerebral, and harder yet to determine whether there may not be laceration of the cortex as well as a meningeal hemorrhage. Of two cases seen once on the same day one was a simple meningeal hemorrhage, the other a meningeal hemorrhage with cortical laceration. Both presented practically the same symptoms except that the latter showed marked delirium, but he was alcoholic.

Cases of head injury with symptoms at first too slight to suggest operation should be carefully watched, as serious symptoms may develop after a long period. Some years ago he had seen a patient in New Hampshire who three months before had fallen, striking his head. He complained of headache, but was able to attend to business and to make weekly trips to Boston until about a fortnight before. Then he began to be stupid, developed hemiplegia and became comatose. An operation showed an extensive meningeal hemorrhage, but the patient had grown too weak to survive it.

Dr. J. J. PUTNAM said that in the main he agreed fully with Dr. Sachs' excellent conclusions. He felt sure that even quite prolonged unconsciousness extending over several days was no proof that the patient would not recover, or that operation was called for.

In one case of this sort, where an elderly lady had struck her head heavily against a beam on going down a steep and dark flight of cellar stairs, a prolonged unconsciousness of this sort had apparently been lessened by a lumbar puncture and the patient's improvement dated from that operation, although there had been, previously, periods of oscillation in her condition, and at that time the outlook appeared very bad.

Dr. Putnam could not agree with Dr. Courtney that subdural bleeding was not a substitute for operation in certain cases. He had seen one patient, also a somewhat elderly lady, who had a fairly circumscribed and massive clot directly over the Rolandic area, resulting from a severe fall on the back of the head.

Dr. Putnam also said that if he understood Dr. Sachs rightly, he could not quite agree with him that it was unimportant to differentiate between focal symptoms due to hemorrhage and similar symptoms due to contusion and laceration. It might not be possible to make this diagnosis, but if it could be made, it would affect the decision as to operation.

He also thought that edema, due to imbibition of fluid on the part of the injured nerve-elements, accounted for many symptoms, and might mislead the observer as to the cause of increasing stupor, especially if coming on late.

Finally, the speaker thought that whereas an exploratory operation in which the dura was not opened might frequently be justifiable, it became a much more serious matter to go below the dura. Sometimes, notably in one case where the operation had consisted only in a free incision of the scalp, the speaker thought that the extensive bleeding had been of real service.

Dr. G. L. WATSON. Dr. Sachs has summed up the present status of operative interference very clearly. It is satisfactory to hail the decadence of the diagnoses, concussion and contusion. The deciding question is one which surely requires neurological as well as surgical knowledge for its solution, namely, Does a lesion exist in an accessible region, for the relief of which operation will be more effective than the unaided efforts of nature? Like other gentlemen present, I should dissent from Dr. Courtney's view that no subdural hemorrhage should be included in the class of lesions requiring operation. I should also disagree with Dr. Bullard, who apparently regards an unconsciousness of twelve hours' duration as in itself sufficient indication for operation.

The following symptoms are, in my opinion, in themselves not sufficient to justify operation: (1) Continued unconsciousness, not deepening. (2) Paralysis appearing immediately and not increasing. (3) Inequality of pupils. (4) Delirium and restlessness. (5) The presence of fever. I have seen an enormously dilated pupil disappear within twelve hours with no further symptoms, and perfect recovery follow. I have seen perfect recovery more than once after unconsciousness had been prolonged for days, and can recall many cases in which paralysis, immediately appearing, has cleared up without further complication. Time will not allow going into the details of these cases.

Among the conditions indicating operation I should include: (1) Deepening initial unconsciousness, or unconsciousness coming on after an interval and deepening into coma. If no other localizing sign accompanies, the seat of the injury should be chosen for operation. (2) Spread or increase of initial paralysis or the onset of paralysis after an interval, this points to hemorrhage. In the presence of this condition the possibility that bruising and edema alone are present does not suffice to contra-indicate operation. (3) Jacksonian attacks. (4) A dilated pupil on one side accompanied by paralysis or spasm upon the other

(middle meningeal hemorrhage). (5) Punctured or definitely depressed skull. (6) The question whether simple fissures and moderate depressions of the skull require operation demands, as Dr. Sachs has intimated, surgical rather than neurological judgment. I agree with him that the benefit of the doubt should be here given to operation in view of the many cases in which exploration of such injury reveals widespread and serious conditions likely to prove a future menace.

Dr. SACHS. In concluding this discussion I wish to thank the members of the Society for the consideration which they have given to the various points raised in the paper. It is impossible to respond to every one of the preceding speakers and I can do no more than select one or two remarks for final comment. I am glad to have Dr. Putnam call my attention to the importance of brain edema in traumatic cases, and I believe that up to the present time sufficient attention has not been paid to this special condition. I have no doubt that edema is responsible for many of the symptoms.

In spite of what Dr. Lund has said, I cannot hold the surgeons altogether blameless for the slow advances made in cerebral surgery, nor can I agree with Dr. Lund in this that very little can be done with a jelly-like mass such as the brain is, whereas so much could be done with the tissue as firm as is the gut. First of all, the surgeon is not called upon always to treat the jelly-mass, viz., the brain; he is more often called upon to treat the dura and this is surely more firm tissue, or firm enough, at least, to handle carefully and skilfully. It is of, at least, as much dignity as is the peritoneum, and we all know what the surgeon has done for this. Moreover, in the mere matter of maintaining the natural heat of the brain, the importance of which Horsley has dilated upon, compare the care given to the gut by the average surgeon with the absolute neglect of this one factor in the case of brain operations. Horsley is one of the few, if not, perhaps, the only one, who has given due weight to the maintenance of the natural heat of the brain during an operation. I cannot help, therefore, reiterating that up to the present time the gut has appealed very much more to the surgeon than has the brain and I believe that if brain conditions were studied as faithfully by the surgeons as have been the conditions of the abdominal viscera, the drainage of the cranial cavity would not be the stumbling block to successful operation which it appears to have been.

Granted that the conditions are not altogether favorable to great success in brain surgery, the speaker believes that by active co-operation of the surgeon and the neurologist far greater success can be obtained than has been obtained hitherto, particularly in affording relief in the cases of cerebral traumatism. On the whole, however, the conservative surgeon is the one whose record will be the best in the end.

Recent Literature.

A Compend of Medical Chemistry. By HENRY LIEHMANN, A.M., M.D., Professor of Chemistry in the Woman's Medical College of Pennsylvania and in the Wagner Free Institute of Science. Fifth edition, revised. Philadelphia: F. Blakiston's Son & Co., 1905.

The fact that this little work has reached a fifth edition is evidence of its popularity. It is, however, nothing more than an outline of organic, inorganic and medical chemistry, and it doubt will best serve its purpose as an adjunct to the didactic teaching of the author.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, FEBRUARY 15, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Faddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

MENTAL FATIGUE IN SCHOOL CHILDREN.

THE question of mental fatigue in school children is exciting the interest of both parents and educators. There has long been a feeling current that the ordinary school hours, including a morning and a part of the afternoon, were fatiguing and hence perhaps harmful to the ordinary school child. This, taken in conjunction with such study as is prescribed outside of school hours, has, in certain quarters, been looked upon as a distinct over-taxing of a developing child's mental powers. Fortunately, it is possible to determine with a certain degree of accuracy the facts in the situation, and this attempt has been undertaken by various persons.

A paper of interest in this connection is one by Dr. Joseph Bellei of the Board of Health of Bologna, Italy. For a number of years Dr. Bellei has been interested in the exact determination of the degree of mental fatigue which school children suffer. He has published several articles on the subject, the last of which appears in the *Lancet* of Feb. 3. In this research he has compared the mental fatigue produced in children by the afternoon session, when there is but a short rest between the work of the forenoon and the afternoon, with the conditions when this rest is greater. In one set of children the interval of rest was from twelve to quarter before one, and in the other from twelve to two. In carrying out his experiment Dr. Bellei used a method of dictation which he employed in 1900 under similar conditions, noting among other things the number of mistakes made at various periods of the day. For example, a first dictation was given to the children at two o'clock, another at quarter before three, and a third at half past three. Among

other interesting results of the research, it was found that at a boys' school, after three quarters of an hour of study, the children made a very considerably greater number of mistakes than at the moment of beginning the lessons. In general, the results showed that from the time of beginning the afternoon lesson at two o'clock to the closing of school at half past three the mistakes augmented by .521, whereas the percentage of boys who did not make mistakes diminished by 30.4, and the average number of mistakes for every boy increased from 1.01 to 2.62. Comparing these results with a very similar series of observations made in 1900, it was found that the work done in 1905 was slightly better than in 1900, but not sufficient to alter general conclusions. The same results were likewise obtained from investigations in girls' schools.

Summarizing the general results of the study, it appears that there is little difference between the quality of children's school work during the latter part of the afternoon session, whereas a rapid fatigue is manifest in the three quarters of an hour from two o'clock to quarter before three. It is therefore argued that the children become so tired after a short amount of afternoon work that their exercises are full of mistakes, in marked contrast to the conditions existing in the morning sessions. It furthermore appears that at the beginning of the afternoon session the children are for an exceedingly short time capable of doing their best work, but that fatigue almost immediately supervenes. These results are essentially confirmatory of those obtained under similar conditions in 1900, and Dr. Bellei thinks he is justified in assuming the probable correctness of his deductions, which are, as expressed also in a previous publication, "The work done by the children during the afternoon lessons is, on account of the great mental fatigue which it involves, of no advantage to their instruction, but is full of danger to their health."

This is possibly a somewhat strong statement of the case. We also incline to think that it might be well to distinguish between actual mental fatigue and lack of concentration, which might, under certain circumstances, account for mistakes made preceding the hour of dismissal. It requires but small experience with children to recognize the curious difficulty they have in fixing the attention upon a subject for any length of time, particularly if that subject be one of small inherent interest. Such a wandering of attention is, however, not to be forthwith construed as evidence of fatigue. Much of the best of our

modern teaching, which possibly can be less well carried out in public schools, consists in exciting the interest of children in the particular work in hand. If this be lacking, teaching becomes a practical impossibility after a short period of application.

In general, however, it is evident that the sort of work which this paper of Dr. Bellei presents is extremely useful in determining certain of the difficult problems underlying elementary education. In such investigations, however, the fact should not be lost sight of that many elements enter into a condition which may, by the tests employed, be regarded erroneously as pure fatigue. It would, for example, be interesting to observe the results in a class of children who were deeply interested in the work they were doing as contrasted with a class who had no such incentive and were looking eagerly forward to the relaxation at the close of school.

PREGNANCY AND DIABETES.

ALTHOUGH the coincidence of diabetes and pregnancy is of relatively frequent occurrence, the first recorded cases have only recently been brought to the notice of the profession, and it is only within the past few years that a number of articles have appeared on the subject. From a study of published cases it would seem to result that the existing conditions are so varied that it is a most difficult matter to draw any general conclusions.

It is well known that many women become temporarily glycosuric during their pregnancies and, for this very reason, it is a most delicate matter to decide where the glycosuria of pregnancy ends and where true diabetes begins. For the clinician, however, this question is of the highest import, because, in the first case, he is dealing with a benign and transitory affection where no treatment is required, while in the latter, on the contrary, the prognosis is a matter of much reserve, a severe diet must be observed and a constant watch kept for the well-known complications of diabetes.

Some time ago Rospie pointed out the differential diagnosis and made the following observations. In glycosuria of pregnancy the amount of urine is not increased, sugar is present in small amounts (25 cc to 6 gm. per liter), it is not accompanied by any of the usual symptoms of diabetes, such as polydipsia, boulimia, anorexia, loss of flesh, or severe disturbances of the nutrition. It makes its appearance with the preg-

nancy and disappears completely as soon as nursing is begun.

It has been upheld, and some cases seem to prove, that abundant, prolonged and repeated glycosuria of pregnancy might favor the occurrence of true diabetes in the future, but, however this may be, the prognosis of glycosuria of pregnancy, as met with in about 66% of all cases, is usually of a mild type and in no way compromises the general health of the woman and does not necessitate any medical treatment.

It should be distinctly understood that this does not apply to cases of true diabetes, and here again, the complications to which diabetic subjects are liable appear to have been very greatly exaggerated. For example, all diabetic females are not necessarily sterile, as has been upheld by some authorities, and so long as no lesions of the uterus or adnexa exist, which ordinarily prevent conception, pregnancy is always a possibility. When this has taken place, its evolution will depend largely on the form of diabetes present.

In the mild types of the disease gestation will go on to term in a normal way, but in the acute and sub-acute types, abortion or premature labor is to be feared.

The post-partum is usually prolonged, the vitality of the product of conception is frequently low and the fetus may die in utero or be born between the seventh and ninth months in a weakened condition.

In the majority of cases there is a calm in the disease during the first half of gestation and then suddenly an aggravation of the pre-existing symptoms takes place during the seventh to the ninth month. It is also at about this time that the accidents due both to pregnancy and to the diabetes arise, and it is safe to say that their prognosis is exceedingly bad.

These accidents more especially consist in hemorrhages, which may be so profuse as to cause severe anemia and thus favor infection, which often results in loss of life. Infectious processes usually supervene after labor and in no way differ from those arising in females who are not diabetic. There is, however, a point to be noted, namely, that of sudden death from syncope. This usually occurs from the third to the fifth day post partum and the cases long since collected by Duncan tend to show that diabetes in the pregnant woman may result in fatal consequences. Out of 15 cases, 11 ended in death of the patient shortly after delivery, in four an attack took place three to four days after labor, while in one death occurred within from six to eight months after

wards, but could not be directly attributed to the pregnancy.

The question of allowing a diabetic subject to nurse is of considerable import, but here again no absolute rules can be formulated. It can only be said that, in the interest of the child, nursing may be allowed when the diabetes is slight and when no other affection in the mother contraindicates it, such as anemia, tuberculosis and so forth. For that matter nothing is easier than to obtain an exact idea of the condition of the mother's nutrition, and should it become affected and the diabetic process aggravated, the infant must be taken from the breast.

MEDICAL NOTES.

RESTRICTIONS ON THE USE OF X-RAYS. — At a recent meeting of the French Academy of Medicine, on motion of M. Chauffard, it was unanimously voted, after a full discussion, that the medical application of x-rays by persons who were not doctors of medicine, *officiers de santé*, or duly qualified dentists, should constitute an act of illegal practice.

PROF. KARL VON NOORDEN TO SUCCEED PROFESSOR NOTHNAGEL. — It is announced that Professor von Noorden has been selected as the late Professor Nothnagel's successor in the University of Vienna. Professor von Noorden leaves the position of chief of the medical clinic in the Municipal Hospital of Frankfurt-am-Main to accept this chair in Vienna which must be regarded as one of the most important in Europe.

PRACTICAL DISINFECTION. — The Illinois State Board of Health has recently issued a circular entitled "Practical Disinfection," which concerns itself with disseminating knowledge regarding the best means of disinfection of infected premises. Several methods are discussed in detail and instructions given on the means of carrying them out. Insistence is very rightly laid upon the futility of imperfect disinfection. The circular should prove of value beyond the region which it is designed primarily to affect.

MEDICAL MEMBERS OF PARLIAMENT. — According to a report in a late number of the *British Medical Journal*, the recent English parliamentary elections have gone badly for medical candidates. Sir Michael Foster, Dr. C. F. Hutchinson, Surgeon-General Evatt and Dr. J. Court have all failed to secure election. On the other hand, Mr. R. J. Price, Dr. V. H.

Rutherford, Dr. Ronald Rainey and Dr. Pollard, all standing as Liberals, have been successful in replacing former conservative members.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Feb. 14, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 51, scarlatina 30, typhoid fever 7, measles 166, tuberculosis 34, smallpox 0.

The death-rate of the reported deaths for the week ending Feb. 14, 1906, was 20.68.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Feb. 10, 1906, was 244, against 233 the corresponding week of last year, showing an increase of 11 deaths and making the death-rate for the week 21.38. Of this number 131 were males and 113 were females; 236 were white and 8 colored; 165 were born in the United States, 72 in foreign countries and 7 unknown; 58 were of American parentage, 155 of foreign parentage and 31 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 56 cases and 4 deaths; scarlatina, 28 cases and no deaths; typhoid fever, 4 cases and 2 deaths; measles, 182 cases and 5 deaths; tuberculosis, 49 cases and 37 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 35, whooping cough 3, heart disease 30, bronchitis 5 and marasmus 4. There were 16 deaths from violent causes. The number of children who died under one year was 43; the number under five years, 65. The number of persons who died over sixty years of age was 43. The deaths in public institutions were 89.

There were 2 deaths and 1 case reported from cerebrospinal meningitis during the week.

INDUSTRIAL SCHOOL FOR CRIPPLED AND DEFORMED CHILDREN. — A fair was held Feb. 14 and 15 in aid of the Massachusetts Industrial School for Crippled and Deformed Children.

ANNUAL MEETING. — The seventeenth annual meeting of the Boston City Hospital Alumni Association was held on Feb. 7. Interesting medical and surgical cases were shown in the amphitheater of the hospital between eleven and one o'clock after which about 125 men partook of an excellent luncheon kindly provided by the trustees.

The business meeting was held at the Hotel Tulleries at 6.30 p.m. The following officers were

elected: President, Dr. George A. Leland; Vice-President, Dr. George T. Tuttle; Secretary, Dr. William H. Robey, Jr.; Treasurer, Dr. William H. Prescott; Member of Executive Committee for five years, Dr. George L. West.

The president, Dr. Charles H. Williams, presided at the dinner. One hundred and thirty-five men were present.

The after-dinner speakers were Dr. Charles W. Eliot, President of Harvard University, Rev. Dr. George A. Gordon of the Old South Church, Mr. Harvey N. Shepard, Dr. David W. Cheever, Dr. Samuel J. Mixer of the Massachusetts General Hospital, Dr. J. Baptist Blake and Dr. George A. Leland, the president-elect. A song by Dr. Baptist Blake was given by Dr. Paul Thorndike. Mr. Fred Bancroft sang some Irish and English ballads.

GRADUATING EXERCISES OF MASSACHUSETTS HOSPITAL TRAINING SCHOOL.—The graduating exercises of the Training School for Nurses of the Massachusetts General Hospital were held in the new Out-patient building on Wednesday evening, Feb. 7, at 8.30 P.M. Dr. H. C. Walcott, chairman of the Board of Trustees of the hospital, presided and presented the diplomas to the graduating class. The class taking the full three years' course numbered 16 and those taking the thirteen months' postgraduate course numbered 10. Prof. Jeffrey R. Brackett of Simmons College made an address to the members of the training school and their guests who were present to the number of about 300. Professor Brackett laid especial stress upon the opportunity of the nurse in doing educational work among those with whom she is thrown in contact, and her chance as an individual in creating a sane and healthy public sentiment.

Miss Dolliver, superintendent of the training school, made a report of the year's work. After this the ceremony of the presentation of the diplomas took place. Music was furnished by the Albion Quartette.

After the graduating exercises there was a reception held on the floor above which gave an opportunity for reunions of many of the former graduates.

NEW YORK.

CHRISTIAN SCIENTIST NOT EXEMPT FROM JURY DUTY.—Holding that a Christian Science leader is not exempt from jury duty, Justice MacLean of the New York Supreme Court has imposed a fine of \$100 on John C. Lathrop for neglecting to appear at the December term of the court for

jury duty, on which he had been summoned. Lathrop, who is a prominent exponent of Eddyism, claimed that he was exempt on the same ground as practising physicians.

A CENTENARIAN.—Rebecca Dickson, known as the oldest negress in Greene County, died at Catskill, N. Y., on Feb. 9, at the age of one hundred and one years. She is survived by her husband, who was ninety-eight years old in September last.

POISONING BY WOOD ALCOHOL.—On Feb. 7 one military prisoner confined in the cells of Castle William, on Governor's Island, was killed and another made dangerously ill by drinking wood alcohol, which had been smuggled into the prison.

OPENING OF WILLARD PARKER HOSPITAL.—The new laboratory building and the remodeled Willard Parker Hospital of the Health Department, located at the foot of East 16th Street, were formally opened by Commissioner Darlington on Feb. 9, and the buildings were inspected by a large number of physicians to whom invitations had been sent. The new laboratory, which is considered one of the best equipped in the country, offers admirable facilities for pathological study and bacteriological research. It is a handsome building, with seventy well-lighted rooms. The Willard Parker Hospital, for diphtheria and scarlet fever, has been made fireproof and very considerably enlarged and improved.

ANNUAL MORTALITY IN STATE.—The last bulletin of the State Department of Health shows that during the year 1905 there were a little over 137,000 deaths in the state. The daily average of deaths was 376, as against 380 in 1903 and 350 in 1901. Allowing for the increase in population, the death-rate for 1905 comes to 17.1 per thousand, which is about the average of the past five years. It is a better showing, however, than in 1901, when the death-rate was 18.2. Pneumonia caused more deaths than any other one disease, the number attributed to it being 14,157, as against 13,531 in 1904 and about 9,000 in 1903. Pulmonary tuberculosis comes second as a cause of death. The mortality from cerebrospinal meningitis amounted to 2,566, as against 1,700 in 1904. Scarlet fever, after four years of high mortality, has suddenly decreased by 1,477, while diphtheria has the smallest number of deaths on record from that disease. Bacterial disease caused 8,870 deaths. The infant mortality was 27.54 of the total. There were 24,000

deaths of those more than seventy years old, and in rural districts one third the total mortality occurred in aged persons.

MEDICAL SOCIETY, STATE OF NEW YORK. — At the annual meeting of the Medical Society of the State of New York, which was held in Albany on Jan. 30 and 31 and Feb. 1, the plan previously agreed upon for the merging of the State Medical Association with that body was carried out. The State Association and the various County Associations now pass out of existence, while the general plan of their organization has been engrafted upon the State Society and the County Societies in affiliation with it. Every member of a County Society becomes by reason of such membership a member also of the State Society and is required to contribute to the support of the latter. The *New York State Journal of Medicine*, the monthly publication established by the State Association, is to be continued, and in it will be printed all the papers read at the meetings of the State Society. The following officers were elected: President, Dr. Joseph D. Bryant of New York (re-elected); First Vice-President, Dr. Herman R. Ainsworth of Addison, Steuben County; Second Vice-President, Dr. Frederic C. Curtis of Albany; Third Vice-President, Dr. Allen A. Jones of Buffalo; Secretary, Dr. Wisner R. Townsend of New York; Treasurer, Dr. Alexander Lambert of New York. At a public meeting held on the first night of the session addresses were delivered by ex-President Grover Cleveland and the Hon. St. Clair McKelway, of the Board of Regents, University of the State of New York.

Obituaries.

GEORGE RYERSON FOWLER, M.D.

DR. GEORGE RYERSON FOWLER, the eminent surgeon, died on Feb. 6, in the Albany Hospital, where he had undergone two operations for appendicitis with complications. While on his way to Albany on Jan. 29, to attend the annual meeting of the Medical Society of the State of New York, he was taken ill, and the same night the first operation was performed by Dr. Van der Veer. Dr. Fowler was born in Brooklyn, N. Y., on Dec. 25, 1848, and was graduated from Bellevue Hospital Medical College in 1871. His professional life was passed in Brooklyn, and for the first two years after his graduation he was on the staff of the Central Dispensary. He was the first visiting surgeon to the Bushwick and East Brooklyn Dispensary on its organization in 1878, and presiding officer of its medical staff until 1887, when he was appointed consulting surgeon.

For a number of years he was surgeon-in-chief of the Brooklyn Hospital, and at the time of his death he was attending surgeon at the Methodist Episcopal (Seney) Hospital and the German Hospital, and consulting surgeon to the Norwegian, St. Mary's, Bushwick and St. John's hospitals. He was also a member of the State Board of Medical Examiners. In 1877 Dr. Fowler was commissioned assistant surgeon, and in 1886 surgeon, of the 14th Regiment, National Guard of New York. In 1902, he was appointed surgeon of the National Guard, with the rank of colonel and brevet brigadier-general, on the staff of Major-Gen. Charles F. Roe. In 1885 he established classes for instruction in first aid to the injured at the New York State Camp at Peekskill, and this movement shortly resulted in the issuing of an order from the adjutant-general's office in Washington for similar instruction at all military posts in the United States. In 1890 the Red Cross Society of Brooklyn was organized, with Dr. Fowler as president, and the Society has done excellent work in instructing members of the police force how to act in cases of accident. In the Spanish-American war Dr. Fowler served as chief surgeon with Gen. Fitzhugh Lee, and he organized hospitals in Havana when that city passed into the control of our army.

Dr. Fowler was one of the founders of the Brooklyn Anatomical Society, its first secretary and later its president. Among the other positions in medical societies which he held were those of president of the Kings County Medical Society and vice-president of the New York Academy of Medicine.

He possessed remarkable skill as an operator and was regarded as a leading surgical authority, especially in abdominal surgery. Dr. Fowler was a man of indefatigable industry and was ever ready to give to the profession the benefit of his enormous experience. Consequently, he was a voluminous and highly esteemed writer on surgical subjects, and an elaborate treatise on surgery, by him, in two volumes, is now on the press in Philadelphia.

JOHN SLADE ELY, M.D.

THE death of Dr. John S. Ely of New Haven, Conn., occurred last week under peculiarly tragic circumstances. Shortly before his death he was thrown from a horse on a hard pavement, fracturing his skull and never recovering consciousness. An operation proved unavailing. Dr. Ely was one of the leading physicians of his city, and at the time of his death was professor of the theory and practice of medicine in the Yale Medical School. He received his education at the Sheffield Scientific School, graduating in 1881, and his medical training from the College of Physicians and Surgeons of New York, graduating in 1886. He was forty-six years old at the time of his death, and had established for himself an enviable position in the profession, both within and without his native city.

Miscellany.

A DEFINITION OF THE PRACTICE OF MEDICINE.

AN important advance has been obtained by the County Medical Society in securing from a court of record a definition of what constitutes the practice of medicine. The definition was framed by Judge Joseph I. Green of the City Court, who stated that he had searched the authorities of the state in vain to find one. It was as follows: "The practice of medicine is the exercise or performance of any act by or through the use of any thing or matter, or by things done, given or applied, whether with or without the use of drugs or medicines, and whether with or without fee therefor, by a person holding himself or herself out as able to cure disease, with a view to relieve, heal or cure, and having for its object the prevention, healing, remedying, cure or alleviation of disease." This definition formed part of Judge Green's charge to the jury in a case in which a woman who sought to recover \$2,000 for malicious prosecution from the County Medical Society, which had brought charges of illegally practising medicine against her. Before announcing his definition Judge Green said: "The court has examined the definitions which appear in the various dictionaries, both as to what is meant by the word 'medicine' and what is meant by the term 'practising,' and, having in mind the object of the statute, the court has undertaken to charge in this case what the court deems to be the practice of medicine within the meaning of the statutes and the meaning of the law in this state." The case began nearly four years ago when the Society brought proceedings against the woman, who advertised in the papers to cure acute and chronic disease. Her treatment consisted of manipulation of the spine and general massage, and she accepted a fee of \$2 from several agents of the Society who were sent to her as patients. When sufficient evidence had been secured against her she was arrested and held for trial in the Court of Special Sessions, but when the case came up the defendant was discharged on the ground that it was not proved that she had given any drugs. She finally brought suit for malicious prosecution in the City Court, where, on the strength of Judge Green's charge, the case was decided against her. It is stated that this is the first case of the kind which the County Society has had to defend in five years, although during that time it has prosecuted hundreds of illegal practitioners.

COMMITTEE ON HOSPITAL ORGANIZATION IN NEW YORK.

At present the public hospitals of New York are partly under the management of the Health Department, partly under that of the Charities Department, and partly under that of the trustees of Bellevue and Allied Hospitals, and in response to a general demand from hospital

officials and charity workers the mayor has invited fifteen well-known citizens to act with the Commissioner of Health, the Commissioner of Charities, the Tenement-House Commissioner and the president of the Board of Trustees of Bellevue and Allied Hospitals as a committee to devise a plan of organization by means of which the hospital system may be more simply and advantageously administered. Ex-Controller Edward M. Groot has been requested to serve as chairman of the committee, and its medical members are Dr. Floyd M. Crandall, president of the County Medical Society, and Dr. Charles H. Chetwood. In his letter of invitation to these gentlemen Mayor McClellan states that the City of New York, through its several departments, is about to expend large sums of money for the extension of its hospital service. He goes on to say that the question of proper treatment of its consumptive patients has been widely agitated, with the result that at present both the Department of Health and that of Public Charities contemplate establishing hospitals for consumptives at great cost to the city, while the trustees of the Bellevue and Allied Hospitals also propose to care for this class of sufferers. In view of these extensive plans for the future he considers it most important that the present system should be investigated and improved, to the end that a general scheme of administration may be adopted which will insure to the city a thoroughly practical and satisfactory method of developing its whole hospital service.

THE EDIBILITY OF ANIMAL SPLEENS.

E. T. WILLIAMS (*American Medicine*, Feb. 10), in the course of investigations on animal spleens, found them good to eat. He cooked them in various ways and tested them on his friends. They contain $\frac{1}{2}$ gr. iron and $1\frac{1}{2}$ gr. phosphorus per ounce. When raw they have a pulpy consistency, which renders them unfit to eat. Heat coagulates their free albumin and gives them a consistency to be cut and chewed. They must be eaten quite fresh. They decompose rapidly and cannot be kept over night, even on ice. To be safely eaten they must, of course, be healthy. All infectious diseases are liable to affect the spleen. All diseased spleens should be rigidly excluded. Dr. Williams concludes with general remarks on the dietetic value of spleens as a blood-making food.

The number of spleens available for food purposes is almost without limit. A rough estimate based on the United States Census Report reveals the fact that there are upward of 50,000,000 pounds of edible spleens thrown away yearly in the United States. This includes the spleens of cattle, hogs and sheep. An ox spleen weighs upward of 2 lbs.; a hog's spleen about 1 lb.; a sheep's spleen 1 oz., on the average. It is worth to see what an enormous amount of good food is thus wasted every year. The commercial value of these spleens reckoned at ten cents per pound would be about \$5,000,000 per annum.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, FEB. 3, 1906.

| CITIES. | Reported deaths | | CITIES. | Reported deaths | |

CHANGES AT THE BOSTON CITY HOSPITAL.

RESIGNATIONS.

DR. AENEAS POST has resigned as senior visiting physician at the Boston City Hospital.

DR. FRANK W. DRAPER has resigned as medico-legal pathologist.

DR. EDWARD T. TWITCHELL has resigned as physician to the Convalescent Home.

APPOINTMENTS.

DR. H. L. BURELL has been promoted as senior visiting surgeon.

DR. GEORGE H. MONKS has been promoted as junior visiting surgeon.

DR. F. B. LUND as first assistant visiting surgeon.

DR. F. J. COLTON as second assistant visiting surgeon.

DR. DAVID CHEEVER has been appointed third assistant visiting surgeon.

DR. WILLIAM H. ROBEY, JR., has been appointed medical registrar *vice* Dr. J. N. Cullidge resigned.

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING FEBRUARY 10, 1906.

D. N. BERTOLETTE, medical director. Commissioned medical director, with rank of captain, from April 5, 1905.

H. G. BEYER, medical inspector. Commissioned medical inspector, with rank of commander, from April 5, 1905.

J. E. GARDNER, medical inspector. Commissioned medical inspector, with rank of commander, from Dec. 17, 1905.

C. M. DEVALIS, J. C. THOMPSON and E. L. BENTON, surgeons. Commissioned surgeons, with rank of lieutenant-commanders, from March 3, 1905.

W. M. CARTON, surgeon. Commissioned surgeon, with rank of lieutenant-commander, from March 12, 1905.

F. E. McCULLOUGH, surgeon. Commissioned surgeon with rank of lieutenant-commander, from June 9, 1905.

F. M. FURLONG, surgeon. Commissioned surgeon, with rank of lieutenant-commander, from June 20, 1905.

J. A. GUTHRIE, surgeon. Commissioned surgeon, with rank of lieutenant-commander, from Dec. 15, 1904.

R. T. ORVIS, surgeon. Commissioned surgeon, with rank of lieutenant-commander, from March 1, 1905.

D. B. KERR, surgeon. Commissioned surgeon, with rank of lieutenant-commander, from April 5, 1905.

G. L. ASGAR, surgeon. Commissioned surgeon, with rank of lieutenant-commander, from April 24, 1905.

R. B. HOYT, passed assistant surgeon. Commissioned passed assistant surgeon, with rank of lieutenant, from May 8, 1905.

W. H. RENNE, assistant surgeon. Detached from the Naval Station, Cavite, P. I., and ordered to the "Elcano."

J. R. SYKES, assistant surgeon. Detached from the "Baltimore" and ordered to the "Oregon."

J. P. DEBRULE, assistant surgeon. Detached from the "Elcano" and ordered to the "Oregon."

F. H. S. DEAN, assistant surgeon. Detached from the "Frolic" and ordered to the "Oregon."

C. J. GRIEVE, assistant surgeon. Detached from the "Oregon" and ordered to the "Frolic."

J. M. STEELE, medical inspector. Commissioned medical inspector, with rank of commander, from Dec. 18, 1905.

WARREN TRIENNIAL PRIZE.

MASSACHUSETTS GENERAL HOSPITAL. — The Warren Triennial Prize was founded by the late Dr. J. Mason Warren in memory of his father, and his will provides that the accumulated interest of the fund shall be awarded every three years to the best dissertation, considered worthy of a premium, on some subject in Physiology, Surgery, or Pathological Anatomy, the arbitrators being the physicians and surgeons of the Massachusetts General Hospital.

The subject for competition for the year 1907 is on some special subject in Physiology, Surgery, or Pathology.

Dissertations must be legibly written, and must be suitably bound, so as to be easily handled. The name of the writer must be enclosed in a sealed envelope, on which must be written a motto corresponding with one on the accompanying dissertation.

Any clew given by the dissertation, or any action on the part of the writer which reveals his name before the award of the prize, will disqualify him from receiving the same.

The amount of the prize for the year 1907 will be \$500. No case no dissertation is considered sufficiently meritorious, no award will be made. Dissertations will be received until April 14, 1907.

A high value will be placed on original work.

HERBERT B. HOWARD, M.D.,
Resident Physician.

RECENT DEATHS.

DR. WILLIAM EDWARD SWAN of New York died on Feb. 4. He was graduated from the College of Physicians and Surgeons, New York, in 1890, and practised for a number of years at Saratoga Springs. At the time of his death he was instructor in diseases of women at the New York Post-Graduate Medical School and Hospital.

DR. RICHARD A. TERHUNE, a prominent physician of Passaic, N. J., died from intestinal cancer on Feb. 5, at the age of 77 years. He retired from active practice about ten years ago, but was frequently called in consultation by his fellow practitioners, by whom his opinion was highly esteemed. His son is Dr. Percy A. Terhune, also of Passaic.

DR. NEWELL E. LAXTON of Newark, Wayne County, N. Y., died on Feb. 9. He was graduated from the College of Physicians and Surgeons, New York, 1876, and was fifty-four years of age. At the time of his death he was president of the village of Newark.

BOOKS AND PAMPHLETS RECEIVED.

The Submucous Window Resection of the Nasal Septum. By Prof. Gustav Killian. Translated by E. Edwin Foster, M.D. Reprint.

Poisoning by Wood Alcohol. Cases of Death and Blindness from Columbian Spirits and Other Methylated Preparations. Frank Buller, M.D., and Casey A. Wood, M.D. Reprint.

Manual of Pathology. Including Bacteriology, the Technique of Post-mortems, and Methods of Pathologic Research. By W. M. Late Coplin, M.D. Fourth edition, rewritten and enlarged. Illustrated. Philadelphia: P. Blakiston's Son & Co. 1905.

Memoranda of Poisons. By Thomas Hawkes Tanner, M.D., F.R.S. Tenth revised edition by Henry Lehmann, A.M., M.D. Philadelphia: P. Blakiston's Son & Co. 1905.

Neurotic Disorders of Childhood, Including a Study of Auto and Intestinal Intoxications, Chronic Anemia, Fever, Eclampsia, Epilepsy, Migraine, Chorea, Hysteria, Asthma, etc. By B. K. Rachford, M.D. New York: E. B. Treat & Co. 1905.

Address.

JOHN HUNTER.*

1728 to 1793.

BY JAMES G. MUMFORD, M.D., BOSTON.

IN Scotland have arisen two men, — Hunter and Lister, — great men in the history of surgery. Hunter dominates the eighteenth century, Lister is conspicuous in the nineteenth, — a man destined to grow with the lapse of years. Hunter was greater than his contemporary, Swiss Haller, in his influence on the practice of surgery, though the balancing of great men against each other is profitless. Hunter, Haller, Morgagni, are the famous names for us in the eighteenth century. Morgagni, pathologist; Haller, physiologist; Hunter, pathologist, physiologist, surgeon. It was time for Hunter. Since sixteenth century Vesalius and Paré, experience had been accumulating, research had been extended, books had been written and knowledge had been diffused. Many able surgeons also had lived in this interval. There were active and highly intelligent practitioners. Many were popular teachers and reformers; they devised new instruments and procedures, they perfected old measures, they adopted and utilized new discoveries, they raised the standard of education, and they abolished the barber surgeon. But there was no prophet among them. Haller, indeed, was a marvellous investigator and teacher, but he was not a practical surgeon, and his discoveries came slowly to fruitage. John Hunter was the man for whom the profession waited.

Not long ago, a well-known teacher, in addressing an audience of physicians said "Surgeons in the past have devoted themselves to the studies of anatomy, pathology, bacteriology, but they have neglected physiology. It is to the teachings of physiology that the surgeons of the future must turn for advancement in their art." He forgot John Hunter. An English writer has told us that to Hunter's sound teaching of anatomy, comparative anatomy and pathology, and to the methods he employed and demonstrated to Jenner, Cline, Cooper, Abernethy, Home, Physick and a host of others, the great nineteenth century school of English surgery owes its fame. All that is true, but Hunter did more than that. He was a great philosopher in the broad sense, as well as a student of the natural sciences. To this day his genius dominates and inspires our science. For nearly one hundred years the Hunterian Oration, instituted in 1813 by Baillie and Everard Home has perpetuated the work and teachings of this man and has drawn lessons from his career. So our materials for a study are abundant, and our accumulated knowledge of him is great.

John Hunter was a Scotchman, of good, robust, middle-class stock. He owed a good deal to his ancestry, probably; certainly, many of

his immediate relatives distinguished themselves and showed the advantage of a clean and vigorous heredity. Hunter's father is described as a small farmer living on his own estate, Long Calderwood, in the parish of Kilbride East, Lanarkshire, and there John Hunter was born on the 14th of February, 1728, as he himself always stated. He was the youngest of ten, — five sons and five daughters. James was the eldest of the family; William, the fourth son, was ten years senior to John.

It is always interesting to learn something of a great man's formative years, but of John Hunter's youth we know little. He seems to have been a vigorous, out-of-doors lad, devoted to rural sports, little given to books, but neither indolent nor unobservant. Indeed, how could he have been either? The tireless student and keen observer of the fifties could not well have come out of a dull and obtuse rustic of the forties. They say his mother petted him, which is true, doubtless, for was he not the youngest of ten? And at seventeen he was sent to Glasgow to help straighten out the affairs of a good-for-nothing brother-in-law, — a bootless errand; but fools are not sent on such errands save by the Dr. Pruneros of this world. There is no doubt, however, that Hunter received scant schooling, and that in his young manhood he was ignorant of books, but he was vigorous and ambitious, and his horizon was not limited to the home-farm, for his elder brothers had gone out into the world, and of William he was proud from his youth up. A word about that particular elder brother.

William Hunter was born in 1718, and from childhood was destined for the church. He seems to have been an intelligent, sensible, attractive lad, eager in the pursuits of knowledge. At fourteen he was well advanced in his studies and was sent to the University of Glasgow. He became conspicuous there almost at once, but soon lost his purpose of being a clergyman. Meantime he had become intimate with William Cullen, six years his senior and a student of medicine. The intimacy bore fruit. Cullen, the future great teacher and clinician of Scotland, was astute even in his youth and recognized William Hunter's abilities. So, upon Cullen's urging Hunter entered upon the study of medicine; from his nineteenth year to his twenty-second he was an inmate of Cullen's house. The next year, 1741, he went on further study at Edinburgh, and then went to London to broaden his education and find a wider field for practice. It was a courageous undertaking and marks the man. Scotchmen were then few in London. George II. was still living, Lord Bute did not come to power until two years later, and Englishmen had not yet learned to recognize that the king's favorite kept in his pocket all the offices and all the honors for his favorites, and men from beyond the border.

When William Hunter went to London he had to depend upon his little family for the necessary gifts of brain power, a good education, and an introduction to Dr. James Douglas, an anatomist

* A portion of the introductory chapter on the History of Surgery in the forthcoming System of Surgery, edited by Dr. W. W. Keen.
Read before the Boston Society for Medical Improvement, Jan. 8, 1906.

and obstetrician of some note. Douglas took a fancy to him at once; he received him into his house, made him tutor to his son, employed him as a prosector, secured for him a position as surgeon's pupil at St. George's, and procured for him first-class anatomical instruction under Dr. Nicholls. Douglas died, unfortunately, in the following year, but Hunter continued to live for a time in his family, and rose rapidly in professional esteem. He soon began lecturing on surgery and anatomy, and proved himself one of the ablest and most popular teachers in England. In 1747 he became a member of the Corporation of Surgeons; and in 1748 made a medical pilgrimage on the Continent. Then gradually he gave up surgery, to devote himself to obstetrics, anatomy, physiology and general practice. Late in 1748 his brother John joined him in London and in 1750 he received the degree of M.D. from Glasgow, his alma mater. He was now well launched upon his life work, and there for the present we leave him, with this reflection, that his training and career were quite other than those of his more famous younger brother. He was an accomplished student and a university product. He was bred up in the best traditions of his profession. He was agreeable, spirited, interesting; an effective public speaker and a popular, inspiring, lucid teacher. Dignified, but apt, brilliant and convincing in conversation, he was the friend of eminent men from his first coming to London. The best professional society frequented him; he became a member of learned bodies and he held the respect and friendship of men of all ranks in that eighteenth century England.

John Hunter, such a rough lad as we have seen, went up to London, to his brother William, in the autumn of 1748. He was twenty years old. He went to London of his own motion, stimulated by the growing reputation of his brother and his brother received him kindly. One may fancy the intercourse of this ill-mated pair, but William seems always to have been patient and generous. Such discord as arose was John's doing mostly. The lad was a bear, and very much of a bear he remained to the end of his days, — jealous, rude, outspoken, much self-centered, intolerant; of an ungovernable temper, given to very naughty language, frequent with oaths. In his youth boisterous, a hard drinker and worse, he was fond of horse-play and addicted to low company. I fear; but always kindly, generous, impulsive; a stanch friend, a good hater. His professional ethics were second-rate, his contempt of empty dignities and humbug was shouted from the house-tops. But he was as sound and unreasoning a Tory as his contemporary, Dr. Johnson; and his patriotism was unswerving and articulate. He hated fiddlers, laced ruffles and Frenchmen.

John Hunter was not the first of the brothers to be attracted by William Hunter's work in London. A few years before this his eldest brother James had given up the law and entered William's dissecting room, where he came to be regarded as a promising anatomist, in the course

of a year. But his health gave out; he returned to the home in Scotland and died there. John Hunter was physically sound, — fortunately for him and for us. He plunged into his work with enthusiasm and he clung to it for forty-five years. His brother William found employment for him at once, preparing a dissection of the muscles of the fore-arm in anticipation of his lectures which began three weeks later. The young man had had no previous acquaintance with anatomy, but succeeded so well that he pleased his elder, who continued to encourage him in such studies, until at the beginning of the second session he was given charge of the dissecting room and the instruction of the pupils. So he went on. It is easy to see where he got his knowledge of anatomy, but just where he acquired early that broad knowledge of the allied sciences and of general medicine is not so obvious. John Hunter used to assert, and writers have continued to tell, how he was without training in letters, and was ignorant of what his predecessors and contemporaries did for the science of medicine. It is hard unreservedly to accept such statements, especially when we know that in later life he was a constant associate of learned men and a valued contributor to their discussions. We know, too, that even in 1748 William Hunter was a companion of such men, who made his house a rendezvous, so the younger brother, from his twenty-first year, breathed an atmosphere charged with things good for intelligent minds, and doubtless was stimulated to read as well as to listen and to think. From the first he did his own thinking, though; there can be no doubt about that, as one sees from his givings forth. Few young men have acquired formed habits at twenty, so that we may believe these new friends helped to direct his energies and to stimulate his ambitions. At any rate, his brother had no intention that he should remain a mere hack, and so the year after John's arrival the youth was placed under the tuition of the famous Cheselden at the Chelsea Hospital.

It is worth our while to glance a moment at Cheselden, one of the most eminent of that school of ancient surgery which was passing; for the passing of which Hunter himself was to be in great measure responsible. William Cheselden was himself a pupil of William Cowper, an anatomist and surgeon of Stuart times, and a contemporary almost of Sydenham and Loeke. Cheselden was educated at St. Thomas's Hospital, became an able anatomist and a skillful operator while still a young man, and for more than twenty-five years was regarded as the leading surgeon in England. He perfected the lateral operation for stone; he was the first to operate for artificial pupil; he was a member of the Royal Society, surgeon to St. Thomas's, St. George's and the Westminster hospitals, and the last warden of the Barber Surgeons' Company, immediately before the separation of the surgeons and barbers in 1744. Moreover, he was a kindly, accomplished, forceful, well-bred man; a gentleman of the old school, our fathers would

have called him, an impressive character and a notable teacher. So there we have John Hunter, living with his brother William, the accomplished scientist, and learning to practise under Cheselden, the foremost surgeon in the country, — truly an admirable school for a rude country boy.

The young man's experience of teachers was to be varied further. In 1751, Cheselden retired from the Chelsea Hospital, the year before his death. Accordingly, Hunter transferred himself to St. Bartholomew's, where he became a pupil of Percival Pott, then in early middle age and vigorously at work. Pott was another admirable man, a man worth our acquaintance; a sound teacher, he was not yet known to fame, but was still in the enthusiastic, accumulating stage, when a man can do most for his pupils. He lived to be Hunter's rival and critic, but he always thought honestly, and fought squarely.

Hunter remained with Pott for three years, and then, in 1754, became surgeon's pupil at St. George's, where he was appointed house surgeon in 1756. Meantime, in 1755, his brother had entered him at Oxford, but he, himself, then at the age of twenty-seven, did not relish the idea, and never kept his terms. The tale is often quoted that years afterwards, Jesse Foot, a rival, disparaged him for his ignorance of the ancient classics. Said Hunter, "Jesse Foot accuses me of not understanding the dead languages; but I could teach him that on the dead body which he never knew in any language, dead or living." Hunter was never over-modest, and Foot was a foolish person whose jaundiced "Life of Hunter" you shall read with groans.

Hunter chose St. George's because he had decided to be a surgeon, and that hospital offered the best chance of future promotion. But he never neglected his anatomy in the midst of diverse other pursuits, and kept at work as pupil and tutor in his brother's dissecting room throughout these ten busy years. However little or much of a reader he may have been, he was a tremendous worker in his own line, — laboratory research; and we shall hear how he was content with four hours of sleep, scanty rations and little play. Even in those early years he was discovering things. Among other feats he solved the problem of the descent of the testis in the fetus; he traced the ramifications of the nasal and olfactory nerves; he tested experimentally the question whether veins could act as absorbents; he studied the formation of pus and the nature of the placental circulation, and, with his brother, he proved practically the function and importance of the lymphatics.

"All that brings us to 1759: He was now thirty-one years old; he had worked without ceasing in London for eleven years, and he broke down. That marks the end of his schooling and his youth. From now on we must think of him as the man of action, — army surgeon, collector, investigator, teacher, writer, practitioner and, towards the end, martyr to a fiery temper and a fatal, agonizing disease.

Hunter's break-down in 1759 did not result seriously, though it disturbed his friends and alarmed himself. He was thought to have incipient phthisis, and he determined to find work and a residence out of England for a time. So in the following year he secured a commission as staff-surgeon to Hodgson and Keppel's futile expedition to Belleisle, — the same expedition which Thackeray has rendered forever comic in his account of Harry Warrington chased by the dragons. Hunter returned unscathed, and the next year went to serve with the English forces on the frontier of Portugal. We cannot stop to learn of his army life except to note that for four years he was with the troops, and acquired a great experience in the treatment of gun-shot wounds. He came to regard the presence in the tissues of a bullet as not in itself harmful, — thus coinciding in opinion with his predecessor Paré. He was too intelligent and diligent a man to content himself with the mere discharge of his duties, arduous as they were, but was continually engaged in physiological and other researches. He studied the conditions of the coagulation of the blood, he continued his old anatomical work, and he collected a great mass of memoranda on inflammations. In those years, too, he began his exhaustive researches into the habits, functions and structure of plants and animals. He learned that digestion does not go on in snakes and lizards during hibernation, and that the creatures will die in that season if they are put through vigorous movements; so he was led to an interesting conclusion which he applied to his human patients; namely, that if the powers of a part are diminished through gangrene or local necrosis, stimulants are dangerous since they "increase action without giving real strength." Soon after his return from Portugal he wrote out a catalogue of his specimens, and recorded notes of about two hundred normal and diseased structures. He retired on half pay in 1763, at the end of the Seven Years' War, but those four years were not the least important for health and progress in his life, and he was wont to look back on them with satisfaction. The experience reminds one of what Darwin, Huxley, Beagmont, Reed and other distinguished men have known. There is place in the public service for scientific work of the highest type, as we have learned.

• We find Hunter, then, at the age of thirty-five, in London with a start still to make on a short allowance, but splendidly equipped in courage, ability and training for the task before him. He proposed to be a practising surgeon; meantime he must live. So he began teaching anatomy and operative surgery to private classes and renewed his acquaintance with the resurricane man. Such teaching was his forte. He never enjoyed formal lecturing; indeed, when he took up that work later he did so with dread. He began each course with embarrassment and hesitation, and used to fortify himself with a big dose of laudanum before his introductory lecture. Scant practice and a daily class would have left most men with abundant leisure, but Hunter had

no leisure in life. He began at once the further study of comparative anatomy, and for subjects obtained animals dying in the Tower menagerie and in travelling zoological shows. He worked when ill even. They tell how he ruptured his tendo-Achillis, and while so disabled experimented on the tendons of dogs. He devised the familiar operation of subcutaneous tenotomy, killed the animals at various stages of their convalescence and through those studies ascertained the method and course of tendon healing. Out of such work grew the modern operations of that nature. In 1767, he was made a member of the Royal Society, — a fact noteworthy, since he had as yet published but one brief paper, and his brother William did not receive the honor until several years later. Evidently the great ability of the younger man was already making itself felt. The next year, 1768, he was appointed surgeon to St. George's Hospital and a member of the Corporation of Surgeons, five years after settling to practice; and now he established that routine of daily life for which he was remarkable to the end. All great scientists have been workers, but Hunter worked in a fashion unknown to our incessant modern life even. He rose daily at five o'clock and without waiting for a decent toilet hastened to his private dissecting room. There he worked until nine o'clock, when he snatched a hasty breakfast. He was methodical. From breakfast time until twelve he received office patients, and at twelve promptly, no matter who waited, he went out to make professional calls and his hospital visit. He returned home at four and dined. He ate abstemiously and, for the last twenty years of his life, drank no wine. After dinner he slept for an hour, and at half past five went to work again. Those evening hours were his most effective hours. He kept at it incessantly until after midnight, going to bed between one and two in the morning.

He must have been a cheerful companion for his wife; for he married, of course, and in some fashion managed to beget and rear children. Mrs. Hunter was the daughter of a Mr. Home, a struggling army surgeon, and for this lady, in his early poverty, Hunter had to wait several years. He married her finally against the protests of his worldly-wise brother, whose opposition to the match is said to have been the beginning of that breach which finally separated the two men. John Hunter's wife was a good wife to him, though his selfishness and rough manners must have tried her sorely. She was a pleasant, social body, given to cakes and ale, and rather partial to those fiddlers and Frenchmen whom her husband abominated. Here is a sombre tale of social misadventure: "On returning late one evening, after a hard day's fag, he unexpectedly found his drawing-room filled with musical professors, connoisseurs and *other idlers*, whom Mrs. Hunter had assembled. He was greatly irritated, and walking straight into the room, addressed the astonished guests pretty much in the following strain: 'I knew nothing of this kick-up, and I ought to have been informed of it beforehand;

but as I am now returned home to study, I hope the present company will retire.' " He was a good, old-fashioned British husband, and his sprightly wife remained faithful to him, though he bullied her while he lived, and left her penniless when he died. Mrs. Hunter had a younger brother, Everard Home, twenty years Hunter's junior. The lad became a member of their household, studied surgery under his distinguished kinsman, was taken into his confidence, was made his assistant, partner and executor, grew to fame on his fame — Home was not without ability of his own — and made himself forever infamous, long afterwards, by burning a great collection of the Hunterian manuscripts in order to conceal his own literary pilferings, a scandal with which scientific London blazed in the early years of the last century.

In 1768, then, John Hunter found himself well established; he moved shortly afterwards into his brother's former house, and began to take house-pupils — many of them afterwards famous. Of such pupils were Jenner, Guy, Physick, Lynn and Carlisle. At St. George's he had Abernethy, Cline, Earle and Astley Cooper, and he taught those young men to work as he worked himself. Early in his career, Hunter recognized that, as yet, comparatively little had been done to explain the nature of disease, its significance, its relation to health, its progress and its classification. Again we are confronted with the problem of Hunter's ignorance, of or familiarity with the accomplishments of other workers. Of course, he must have known the broad outlines, the common property of all physicians of his time, but he often seemed to feign ignorance; or what is more probable, he distrusted published conclusions, and had a pretty steady contempt for the capacity and observations of his fellows; not that he trusted himself implicitly, though he thought well of John Hunter; but he used to tell his pupils not to refer to what he had said the year previously, for he reserved to himself the right of changing his conclusions. At any rate, he perceived that medicine was in its infancy, and he undertook the stupendous task of revolutionizing ancient methods of study and launching science anew upon sound and rational lines. He began with fundamentals; he insisted upon a review of anatomy; and he taught that a thorough knowledge of embryology is essential to an intelligent pursuit of anatomy. Not only that, but he perceived the significance of the structure of animals of varying types, and of plants too. He had more than a suspicion of the evolution of species, and their origin, and insisted that a foundation in medical knowledge could be acquired from an exhaustive study only of the comparative anatomy of animal and vegetable life. In such studies and in such teaching he was unwearied. Read his works and you will find an astounding variety of evidence that he had anticipated a hundred modern discoveries, and had constructed hypotheses which have been adopted since as some of the important theories of recent research. Not content with such work

he was indefatigable in his investigation of physiological problems in man, animals and plants. In his own laboratory and with the rough tools at his command he performed experiments and reached conclusions not unworthy of a Harvey, a Haller, a Spallanzani, a Bichat or a Claude Bernard; and he inspired with a like diligence and enthusiasm the few choice spirits who had the wit to appreciate his greatness and the courage to follow his lead. They were young disciples. Among his contemporaries he had no following. What great man's contemporaries ever did become his followers?

Fundamental work was Hunter's great work. It is for such that we hold him in the front rank of all our benefactors. He saw the meaning of science more clearly than any man who had then lived; and he had the genius to make others see that meaning. That marks him as it marks the few rare spirits of his kind to whom men have given ear.

Hunter was not infallible. He made many mistakes; for he strove much and often, and such constant strivings end sometimes in error. But he was luminous and articulate to show the way, not hoping in one short life to reach the goal of all knowledge, but confident that from his Nebo his successors would advance upon the land which to him was vouchsafed as a vision only.

Hunter's method was rigid adherence to deduction founded upon observation and experiment, and his studies embraced an enormous field. Let us pass in brief review some of his better known contributions to science: In 1772, he published his first paper in the *Philosophical Transactions*, an essay on post-mortem digestion of the stomach, in which he explained that phenomenon as a result of the action of the gastric juice. In 1771 and 1778 appeared his essays on the teeth, whose natural history was explained and their diseases exhaustively considered. The work was an authority for three generations. In 1774, he read before the Royal Society a paper on "Birds," describing their manner of breathing; and a paper on the "Stomach of the Gillaroo Trout." During these same years he was busy with investigating the temperatures of animals under varying conditions, and his letters to Jenner, his constant correspondent, describe his elaborate clinical thermometer in a fashion worth your reading. Such investigations led to a delightful paper, which he read before the Royal Society in 1778, on the "Heat of Animals and Vegetables."

Two years afterwards, in 1780, Hunter presented to the Royal Society a paper which precipitated a bitter quarrel with his brother William, a quarrel which was healed a few days only before the elder's death, three years later. John Hunter's paper dealt with the structure and circulation of the placenta, with facts which he claimed to have discovered and established many years before, when working in his brother's dissecting room. Now William Hunter had published the same observations in his work on the gravid uterus in 1775. The he was given and

returned publicly between these two eminent men, and the Royal Society refused to print John Hunter's paper. He acted badly, whatever the rights and wrongs in the case may be. In this same year of 1780 Hunter read before the Society an account of a fetus, dead of smallpox; and a paper on the change of plumage in non-breeding hen pheasants. In 1782 there followed an essay on the organ of hearing in fishes.

Lectures, essays, letters, flowed from him continually during these years, but it was in 1785 that he made the observations and performed the operation for which he is best known to students of surgery.— Hunter's operation for aneurism. The story is interesting and illustrates the man. He happened in that year to be studying the mode of growth of deer's antlers. In July he had a buck caught, and tied one of its external carotid arteries. He observed that the antler which was nourished by the vessel became cold to the touch, and he debated whether this antler would be shed in due course or would be retained longer than usual. To his surprise he found, two weeks later, that the wound was healed and that the antler was again warm and vigorous. He supposed the ligature might have slipped, so he had the animal killed, when on examination he was interested to discover that the ligature held, but that through anastomosis and enlargement of small vessels above and below the occluded part, normal circulation had been restored to the growing antler. From this observation he was led to the conclusion that "under the stimulus of necessity" the smaller arteries are capable of rapid increase in size to perform the function of the larger.

Soon afterwards he had an opportunity of applying to a human patient this newly discovered law. There entered the wards of St. George's Hospital a man suffering from advanced popliteal aneurism, and in approaching the case Hunter debated whether to employ the old method of Antyllus, dissection and double ligature, or to follow the practice of Pott, amputation well above the aneurism, declared by Pott to be the only safe method. Hunter was conservative in his practice. He abhorred meddling surgery, and used the knife when other means had failed only. He felt the operation of Antyllus to be dangerous, and the method of Pott to be needlessly severe. He argued, however, that it would be reasonable to tie the femoral artery at that safe point where Pott would tie it in an amputation. He would not amputate, however, but would count upon the anastomosis for restoring circulation to the leg. He acted upon this reasoning accordingly, and with success. He tied the vessel in that intermuscular space, known since as Hunter's canal, and was gratified after several hours to find that the temperature of the foot had not fallen, but had risen above the normal. The patient procured satisfactory, and six weeks later, with a good and useful leg, was discharged from the hospital. The fame of this operation went abroad and aroused commotion. Promptly Frenchmen and

Italians claimed priority for their countrymen, while many English surgeons, headed by the veteran Pott, denounced the procedure as dangerous and unwarrantable. But it gained ground and became accepted in spite of loud words. Wise men waxed enthusiastic over it, and the Italian Assalini, who saw it first performed, testified that it "excited the greatest wonder, and awakened the attention of all the surgeons in Europe."

In 1783 Hunter had taken a leading part in establishing the "Society for the Improvement of Medical and Chirurgical Knowledge," and several of his papers were read subsequently before that body. In that same year he read to them an admirable paper on phlebitis,—the first paper we have which gives a satisfactory explanation of that affection; and in 1786 he gave to the world his famous book "On the Venereal Disease," a book long awaited by the profession, and an authority for fifty years thereafter. A few months subsequent to its appearance he published his work on the "Animal Economy,"—a collection of important papers consisting of many admirable anatomical descriptions and accounts of numerous original researches in physiology. In 1787, he gave to the Royal Society a paper on the "Wolf, Jackal and Dog," and a second paper, well illustrated, on the "Structure and Physiology of Whales."

In those years Hunter was overwhelmed with a thousand cares, and suffered much in health, so that his writings were few and at long intervals after 1787. In 1792, the year before his death, he contributed to the *Philosophical Transactions* a paper on bees,—the result of his observation on the hive bees, studied for more than twenty years. His last printed book, a book regarded at the time as the most important of his productions, was posthumous, the final editing being done by Everard Home; its title, "A Treatise on the Blood, Inflammation and Gun-shot Wounds, 1794."

Thus, in a few words, I have told something of the more notable things which Hunter did, but the story is very bare. It would be interesting to look out with him upon the world in which he lived, and to learn something of what other men were doing. The influences which bore upon him, and the condition of Europe in that last half of the eighteenth century, were vital and remarkable. Politics and literature, philosophy and science, were undergoing profound impressions. Hunter was no closet student, but a man keenly interested in what was doing, and for long much in the eye of the scientific world. All this must be a passing thought, however, but we may glance again at Hunter's life, his later years, and bring our story to a decent close.

One recalls certain facts, not altogether agreeable or attractive, minor faults of temper and habit. His body was grievously overdriven by an iron will, so that there resulted ill health and a vicious temper, with which he struggled for years. Certain it is that he suffered from angina pectoris, and found little relief. Over-exertion

brought on frequent attacks; and outbreaks of passion, or the attempts to suppress passion, were a constant dread to him. So far back as 1772 he began courses of systematic lectures which were a severe strain upon him, owing to his painstaking method and labored delivery. He published his lectures later, a standard work of immense learning and rare originality.

In spite of his labors and fame he never made much money, and what he did make went for specimens and apparatus. He was one of the greatest collectors ever known, and scoured the world through friends and messengers for the flora and fauna of all lands. Dozens of his letters to Jenner deal with the habits of the cuckoo; he sent a special expedition to the Arctic for specimens of the whale, and he paid five hundred pounds for the skeleton of an Irish giant.

I have said that it was Hunter's conception and teaching of science which mark him the great man, but to his immediate successors and to the casual reader of to-day he is best known for his museum. The Hunterian museum was a means to an end, but it was a magnificent means. Measured in bank notes it cost him upwards of \$375,000. After his death it was sold for \$75,000.

Hunter seems to have valued money as of service only to enrich his collection. Up to 1780 his income ranged between \$5,000 and \$10,000 a year. For a few years before his death it reached \$25,000, and in one year more than \$30,000. Most of his contemporaries regarded his love of collecting as an eccentricity, and his devotion to science as almost a mania. Few perceived the drift of his biological researches, and his investigations in comparative anatomy were looked upon as works of unprofitable curiosity. Even his friend, Sir Joseph Banks, the president of the Royal Society, wrote three years after Hunter's death, that he did not believe the Hunterian collection to be "an object of importance to the general subject of natural history, or, indeed, to any branch of science except to that of medicine."

The collection is estimated to have contained 13,682 specimens: In the physiological department, 7,295; in the pathological, 2,678, and 3,709 fossils. In the year 1800 it was acquired by the Royal College of Surgeons, since when it has been greatly increased, thanks largely to the efforts of its distinguished line of custodians, William Clift, William Home Clift, Richard Owen, J. T. Queckett and William Henry Fowler.

A writer has defined the scope of these labors of Hunter as the explication of the various phases of life exhibited in organized structures, both animal and vegetable, from the simplest to the most highly differentiated. Hunter did not employ comparative anatomy in subservience to the classification of living forms, as did Cuvier, but in order to ascertain the principle which animated and produced those forms,—a principle by virtue of which it appeared that all forms were allied to himself. He was continually asking himself, In what does life consist? He came to teach that "life is a principle independent of

structure, most tenaciously held by the least highly organized beings." Abernethy says he perceived life to be "a great chemist," a power capable of manufacturing a variety of substances into one kind of generally distributed nutriment, and of furnishing from this a still greater variety of dissimilar substances. Hunter found, in short, that there exists in animals, a latent heat of life set free in the process of death. "Mere composition of matter," said he, "does not give life; for the dead body has all the composition it ever had; life is a property we do not understand." As a bar of iron may gain *magnetic virtue* by being placed for a time in a special position, so, perhaps, the particles of matter arranged and long continued in a certain posture eventually gain the power of life. "I inquired of Mr. Hunter," writes Staple, "if this did not make for the exploded doctrine of equivocal generation; he told me perhaps it did; and that as to equivocal generation all we could have was negative proofs of its not taking place. He did not deny that equivocal generation happened."

Hunter held certain interesting views on geology. In water he recognized the chief agent for producing terrestrial changes; but he held untenable the popular notion that Noah's deluge might account for the marine organisms discovered on land. From the diversity of the situations in which many fossils and allied living structures are found he was led to infer that at various periods there had taken place not only repeated oscillations of the level of the land, lasting thousands of centuries, but also great climatic variations. The following striking paragraph of Hunter's is from Butler's essay: "If we were capable of following the process of increase of the number of the parts of the most perfect animal, as they first formed in succession from the very first to its state of full perfection, we should probably be able to compare it with some of the incomplete animals themselves, of every order of animals in the creation, — being at no stage different from some of those inferior orders; or in other words, if we were to take a series of animals from the most imperfect to the perfect, we should probably find an imperfect animal corresponding with some stage of the most perfect." In spite of involved phrasing, this thought, coming to us out of the eighteenth century, is supremely interesting.

Such were some of Hunter's labors and teachings. Like every genius he kept himself young and projected himself beyond his generation. As he advanced in years and grew to fame his fits of temper and intolerance of opposition increased upon him. It was his temper that killed him. He had become unavoidably concerned with medical politics, a field in which he was not calculated to shine. There came to be bad blood between himself and his colleagues at St. George's because he announced that they were neglecting the surgical pupils, and that thereafter, as he was doing most of the work and attracting most of the students, he should not turn in the fees to the common purse, but would keep them for him-

self. The governors of the hospital ruled against his decision, and provided in addition that thereafter no student should be admitted who had not been educated in medicine. This last rule seemed to be aimed at Hunter. It irritated him particularly because, soon after, there came up to London two young Scotchmen, ignorant of the new law, but seeking to be taken on as his pupils. He explained to them the situation but promised to do what he could. For that purpose, on the 16th of October, 1793, bent on seeing his Scotchmen through, he attended a meeting of the hospital board. Ottley tells the story: "Arrived at the hospital he found the board already assembled, and entering the room presented the memorial of the young men, and proceeded to urge the propriety of their being admitted. In the course of his remarks he made some observations which one of his colleagues thought it necessary instantly and flatly to contradict. Hunter immediately ceased speaking, retired from the table, and, struggling to suppress the tumult of his passion, hurried into the adjoining room, where, with a deep groan, he fell lifeless."

It is a pathetic and tragic scene. One fancies the winged words that may have passed, the taunt of that nameless colleague, who was probably in the right, the fury of Hunter, who was probably in the wrong. Rembrandt should have lived and added that picture to his collection. The fate of those two disappointed young Scotchmen has not been told.

Look back the hundred and thirteen years which have passed since Hunter died; think what his life meant for science and what is the estimate placed upon it by the average physician of to-day. The Englishmen have done their best for him, to be sure. Two of his influential relatives established the annual Hunterian Oration, which survives; but in the profession at large he is little more than a myth. A recent publicist says of him, that he stands for a book of surgical lectures, a treatise on venereal disease and the operation for aneurism. He stands for far more. Those things were by-products dropped from the seething laboratory of his brain. He means for us the first and the greatest English-speaking exponent of proper scientific research. He is the father of us all, — physicians, surgeons, laboratory students, — for he wrought mightily in all fields.

John Hunter inspired little personal affection or devotion, though he inspired admiration and respect, — for his was a vast genius. His disciples recognized the genius, few loved the man. With him it was not as with Hippocrates, or Paré, or Boerhaave, or Haller. It was a fiery soul, onrushing hence eager intolerant, unsparing of others as of himself, the body exhausted out of season, the task unfinshed, but his works do follow him. In modern days only have we come to see that sound knowledge and appreciation of science must be sought along those lines laid down through toil, criticism and weariness by the indefatigable John Hunter.

STENOSIS OF THE PYLORUS IN INFANCY. THE REPORT OF A SECOND CASE SUCCESS- FULLY OPERATED UPON. REMARKS.

BY CHARLES L. SCUDDER, M.D.,

Surgeon to the Massachusetts General Hospital, Boston.

IN the BOSTON MEDICAL AND SURGICAL JOURNAL for Dec. 14, 1905, Dr. Townsend and I recorded a case of stenosis of the pylorus in infancy in which an operation had been successfully performed. The operation in the above case was done upon the fourteenth day of the child's life. Attention was directed to the fact that it was the youngest child successfully operated upon for this obstructive lesion.

I wish to record here a second successful case operated upon for this same lesion. I have added to this report certain facts concerning stenosis of the pylorus in infancy and a word upon the technique of the operation of gastro-enterostomy in young babies.

A. L., a patient of Dr. Hsley of Medford, Mass., was born Aug. 1, 1905, a breast-fed baby, apparently healthy, having a birth weight of six and three-quarters pounds. The baby vomited on the third day and continued vomiting each day despite careful modification of the food. The vomitus never contained bile. He was very hungry. The dejections were like meconium. He was somewhat jaundiced. Emaciation became marked. There was a tumor felt to the right and above the umbilicus. There was visible gastric peristalsis. When the child was twenty-three days old, because of the persistence of the above signs, a diagnosis of pyloric obstruction was made.

On the twenty-fourth day a posterior gastro-enterostomy was performed. A tumor, hard, smooth, without adhesions and about the size of the end of an adult thumb, was discovered at the pylorus. The intestine was empty and collapsed. The stomach wall was found to be considerably thickened and very firm. The stomach was larger than usual. The child recovered from the ether anesthesia rapidly; showed little or no signs of shock. He vomited twice the day of the operation, not at all on the second day, once on the third day, not at all on the fourth day, once on the fifth day and twice on the sixth day. After the sixth day there was no vomiting.

The feeding of the child was superintended by Dr. John L. Morse and was begun, according to his record, almost immediately after the operation Aug. 25. He was started with $\frac{1}{2}$ oz. of whey every two hours. This he took eagerly but vomited more or less for the first eight hours. The vomitus contained bile. There was little vomiting after this.

Aug. 26 he was given a mixture of equal parts of water and of modified milk containing 2% of fat, 5% of sugar, .25% of whey proteid and .25% of caseinogen, with 5% of lime water, unpasteurized; $\frac{1}{2}$ oz., every two hours. During the next two days the water was diminished until he was taking the full strength mixture. The bowels moved on the 26th. The first few movements resembled meconium but the last one, on the 28th, contained a few yellow specks. The weight on the 28th was 6 lbs., 12 oz.

Aug. 30 he was taking one ounce at a feeding, had gained 4 oz., and was having three yellow, digested movements daily. The food was then strengthened to 3% fat, 6% sugar, .50% whey proteids, .25% casein-

ogen, 5% alkalinity, unpasteurized; $\frac{3}{4}$ oz. of this mixture and $\frac{1}{4}$ oz. of water, twelve feedings as before.

Sept. 1 he was taking $\frac{1}{2}$ oz. of full strength mixture, was doing well in every way, having three normal movements daily, and weighed 7 lbs., 8 oz.

Sept. 6 he weighed 7 lbs., 12 oz. and was taking 2 oz. at a feeding. The food was then strengthened to fat 3.50%, sugar 7%, proteids 1%, lime water 10%; ten feedings of 2 to 2½ oz.

The striking things to all in the feeding of this case were that the baby was able to take a considerable amount of food so soon after the operation and bear it well. Of course, with an open passage between the stomach and intestine there is no reason why small amounts of food should be given. This has been the usual custom in the past. The feeding was on the same general plan as that of the new-born baby, that is, beginning with small amounts of a very weak food and rapidly increasing the amount and the strength of the food when it is found that the digestion is able to bear it. The great advantage of a proper amount of a suitable food during the first part of the convalescence over the usual starvation plan is shown by the rapid gain in weight, that is, a pound in nine days.

The baby is now four months and a half old, well and strong and weighs 14 lbs.

The accompanying photograph of the child was taken shortly after the operation, before he left the hospital. (See Fig. 9.)

Stenosis of the pylorus in infancy¹ was formerly inevitably fatal. It was not recognized a few years ago as a distinct disease. To-day not only is it possible to make a diagnosis of the condition but it is found to be of more frequent occurrence than was supposed and it is demonstrated to be amenable to operation.

Pyloric stenosis in infants commonly called "congenital stenosis of the pylorus" is a narrowing of the pyloric lumen caused by an hyperplasia of the circular muscle fibers of the pylorus. (See Figs. 1 and 2.) Associated with this muscle change is an increase in the size of the normal longitudinal folds of the mucous membrane. This change in the mucous membrane helps to augment the pyloric obstruction. Associated with these primary changes one finds constantly at autopsy and at operation certain secondary conditions, namely, the dilated or hypertrophied stomach wall and the collapsed intestine.

The facts upon which a diagnosis may be based are as follows: The child appears at birth healthy. A day or two after birth, or upon an average of seventeen days after birth, vomiting occurs. This is usually the first evidence of something wrong and should immediately attract attention. The vomiting is sudden, unexpected, persistent, appears usually after a feeding. The quantity vomited is equivalent to or more than the previous feeding. It is violent and projectile. The vomitus contains no bile, no mucus and no increased amount of hydrochloric acid. There are no evidences of fermentation in the vomited material. A cessation of this vomiting may be associated with a variation in the diet. The tongue is moist and clean. The breath is sweet.

FIG. 7.—Appearance when the operation of gastro-enterostomy is completed. View behind transverse mesocolon. Note the edges of the opening in the transverse mesocolon sutured at two points to anastomotic region.
[From W. J. Mayo, *Annals of Surgery*, November, 1905.]

FIG. 8.—Operation of gastro-enterostomy completed. View from in front. The anastomotic opening shows through. Note the position of this opening.
[From W. J. Mayo, *Annals of Surgery*, November, 1905.]

FIG. 9.—Photograph of the patient whose case is here recorded. Note ample abdominal incision.

The lips are not dry. The child is usually eager for food and cries with pain as the stomach contracts in its attempt to force its contents through the narrow pylorus. Signs of relief from pain appear after the stomach has been emptied by vomiting.

There is *visible gastric peristalsis* (see Figs. 4 and 5) which is especially noticeable immediately after feeding. A cursory examination may fail to discover this peristalsis. It may be simulated by contractions of the abdominal wall. Contractions of the transverse colon have been mistaken for gastric peristalsis.

A *pyloric tumor may be felt*. This tumor is the thickened pylorus itself and is about the size of a filbert. It is situated a little to the right and above the umbilicus. This tumor may be detected under ether, if not palpable without an anesthetic. There is an opportune time for feeling the tumor, namely, when the stomach is undergoing contraction soon after feeding. It may escape detection by being situated above the border of the ribs, concealed by the liver or the distended stomach. An enlarged gland may simulate it.

The child is constipated, little food passing the pylorus. The movements are meconium-like. The abdomen in the region of the stomach above the umbilicus is more or less distended, below the umbilicus the abdomen is sunken, corresponding to the collapsed intestine.

Cases of stenosis of the pylorus in infancy may be naturally arranged in two groups; those of almost complete obstruction and those of partial obstruction.

If a complete obstruction exists there will be little difficulty in making a diagnosis. On the other hand, cases of incomplete obstruction are often very difficult of diagnosis. The condition most likely to be confused with partial infantile pyloric stenosis is infantile indigestion. A discriminating interpretation of the symptoms present will make a diagnosis possible. The existence of positive signs of infantile dyspepsia, namely, the coated tongue, the offensive breath, the evidence of fermentation in the stomach, diarrhea, improvement under medical treatment and dieting and an absence of the positive signs of pyloric stenosis, namely, the characteristic vomiting, a palpable pyloric tumor, visible gastric peristalsis, will ordinarily make a diagnosis possible.

Prognosis — The prognosis of cases treated medically is almost universally fatal. Certain cases are reported by competent medical observers in which the diagnosis of pyloric stenosis has been made. These cases are said to have recovered under medical treatment, but as yet there is no evidence to prove conclusively that in any of these cases pyloric stenosis of the sort under discussion existed.

On the other hand, there are several instances in which the diagnosis of pyloric stenosis has been made, the cases have been treated medically and are said to have been cured, but the subsequent

autopsy or operation has proved that the condition remained practically unchanged.

I am inclined to think that those cases reported by competent observers as having been cured by medical means represent cases of spasm of the pylorus independent of actual anatomical narrowing of the pylorus. It is possible that these cases in which symptoms have been relieved represent instances of partial stenosis due to actual narrowing. Whether these cases have been cured permanently or not remains to be demonstrated.

Treatment. — The treatment of these cases has most often been by medical means, that is, by diet, opium, lavage of the stomach and careful feeding. The surgical treatment has been by pylorotomy, pyloroplasty, division, gastro-enterostomy and careful feeding.

Gastro-enterostomy is the operation of choice. Kocher's gastroduodenostomy subpylorica is physiologically the ideal operation. A "funny" cannot properly be performed under the physical conditions present, the pyloric tumor is too rigid.

Reasons for failure in surgical treatment have been two, first: The child was too weak to undergo successfully any operation, was brought to the surgeon too late; second: the technique has been faulty. Once too large a Murphy button was used. A neglect to excise the mucous membrane in the gastro-enterostomy stoma caused one fatal obstruction. Too long exposure of the preplaced intestine has caused death. One operator had a leaky suture. A perforation of the duodenum resulted after a Loreta operation in one instance. Over-manipulation of the intestines caused one death. The non-excision of the mucous membrane in a pyloroplasty resulted fatally once. In another case there was a kinking of the gut causing fatal obstruction; this followed a pyloroplasty. The earlier recognition of these cases will eliminate the first factor in the surgical failures. The purely operative technical errors are fortunately today avoidable. Even so, taking all cases operated thus far, and there are over sixty, more than half have been saved. The mortality of cases treated by medical means is over 90%.

The parts to be operated upon are very tiny as compared with the adult anatomy. Very delicate manipulation is necessary and it is safer to operate if especially light instruments are employed. The ordinary adult instruments are clumsy. Attention to the following details is important. An operation will almost always be an emergency procedure; consequently the ideal preparatory treatment may have to be curtailed. If there is opportunity, stimulating enemata of salt solution, 3*ss*. brandy 5*ss*. given several times during the day before operation will prove of value. If the stomach is dilated it should be washed with warm salt solution introduced through a No. 10 English soft rubber catheter. If the child has vomited shortly before the time of operation, but if the stomach is not much dilated the washing will be unnecessary. The skin of the abdominal wall should be cleaned first with alcohol.

water and soap and gauze rubbing, rinsed with sterile water and sterilized with warm alcohol (1-70). After the skin preparation is completed the baby should be thoroughly dried and placed on a blanket. The legs, arms and chest should be covered with sheet wadding held in position by small gauze bandages. The employment of a warmed operating table offers great advantages toward the lessening of shock.

Before the administration of the anesthetic every preliminary operative detail should be attended to so that there may be the minimum period of anesthesia. A skilled anesthetist should be employed. Complete anesthesia is necessary that certain accidents in technique may be avoided. Having confirmed the diagnosis the incision should be made large enough to allow of easy access to the parts sought, with a minimum of trauma to the wound edges. Gentleness in the manipulation of the parts involved is absolutely essential. No organs should be lifted from the abdominal cavity. If possible the liver, stomach, as a whole, and transverse colon should be pushed gently upward under the diaphragm while those parts of the stomach and the jejunum to be united are properly clamped. These clamped portions only are permanently exposed for the carrying out of the operative procedure. The remainder of the abdominal contents should be protected from loss of heat and soiling by a sterile towel.

The usual posterior gastro-enterostomy is done with thread and needle, practically the Moynihan method.²

In the case recorded in this communication and in the case recorded in this JOURNAL, Dec. 14, 1905, I made the anastomosis without jejunal loop as close to the origin of the jejunum as possible.

The seat of operation is well shown in the accompanying illustrations by Mayo in Figs. 6, 7 and 8. I did not employ the technique of piercing the attachment of the omentum to the stomach, illustrated in these plates. These plates are introduced here as they illustrate more accurately than any hitherto published, the seat of operation, the mesocolon sutures and the ideal situation of the stoma, after the completion of the operation.

The superficial sutures closing the abdominal parietes should be removed a little earlier than in the adult for they tend to cut out. The proper feeding of the baby after this operation is most important. I believe that the diet should be under the immediate supervision of one skilled in the feeding of infants.

Protection of the small infantile body from loss of heat, speed in operating, an ample incision, a minimum of trauma to abdominal contents and wound, the use of a delicate clamp to insure cleanliness and hemostasis, skilled feeding after operation, — these are the salient factors which will minimize shock after the performance of gastro-enterostomy in young babies whose normal resisting power is reduced by starvation.

THE "HOME SANATORIUM" TREATMENT OF CONSUMPTION.*

BY JOSEPH H. PRATT, A.M., M.D., BOSTON.

Physician to Out-Patients, Massachusetts General Hospital; Assistant in the Theory and Practice of Physic, Harvard University.

SOMEONE has said, "There are two kinds of consumption — that of the rich and that of the poor. The former is sometimes cured, the latter never." This still indicates the feeling of most physicians. The attempt to cure tuberculosis in the homes of the poor has seemed well nigh hopeless. Here and there, however, solitary workers like Dr. Flick of Philadelphia have obtained admirable results even in the slums of a great city.

As Dr. Osler stated in his lecture before the Phipps Institute, "The problem of tuberculosis is in its most important aspects a home problem. The vast majority of all tuberculous patients must be treated in their homes."

The success of the sanatorium and climatic treatment of consumption is universally recognized. Yet the essential feature of the sanatorium treatment is careful regulation of the details of the daily life, and the essential feature of the climatic treatment is life in the open air.

FIG. 1. Street in congested part of Boston. Photograph taken in front of patient's house.

In warm climates and in cold, at low altitudes and at high, consumption has been successfully treated wherever the out-of-door life has been adopted, and the modern method of treatment followed.

Since 1891 Dr. Bowditch has been demonstrating at the Sharon Sanatorium that consumption can be successfully treated in this supposedly unfavorable climate.

Dr. Millet of East Bridgewater was the first to advocate out-of-door sleeping in a harsh climate. In January, 1900, he published an important paper which bore the significant title, "The Night-Air of New England in the Treatment of Consumption."¹ It would be well if the truths contained in Dr. Millet's paper could be impressed upon every New England physician called upon to treat this disease.

Last winter I became acquainted with the

methods used by Dr. C. S. Minor of Asheville, N. C., in carrying out the hygienic-dietetic treatment among private patients outside of a sanatorium. The regulation of the daily life, the discipline enforced and the results obtained by Dr. Minor compare favorably with those of the best sanatoria. I became convinced that it was possible to carry out the same system in the homes of the poor even in a crowded city. For the opportunity to submit my plan to a practical test I am indebted to the Rev. Elwood Worcester and to Emmanuel Church for financial support.

The reason that the results of home and dis-

her duties. She should be the family's wise counselor, kindly and tactful, yet a good disciplinarian.

The class should number but a few members; I think the limit should be twenty-five. It should never be forgotten that it is the individual, not the disease, that needs treatment.

We have been fortunate in having a small class and so we have come to know our patients not simply as, "this case of fibrous phthisis," and "that case of pyopneumothorax," but as "Elmer" and "Patrick."

The class began the first of July, 1905. Most of the applicants for membership were referred to us by the Out-Patient Department of the Massachusetts General Hospital.

The rule was established that no one would be accepted until the clinical diagnosis was confirmed either by finding the tubercle bacilli or by a positive tuberculin test. There has been, however, no difficulty in demonstrating tubercle bacilli in the sputum of all our patients on admission to the class.

Aid has been refused to none. Those who were too ill for home treatment have been visited by our nurse until admission could be secured to some hospital or until transferred to the District Nursing Association. We have placed consumptives in the Carney Hospital, the House of the Good Samaritan and the Free Hospital for Consumptives.

Admission to the class has not been limited to favorable cases. In fact, only one of the patients was in the incipient stage of the disease.

All of our patients have been poor. None could afford even the \$4.00 per week charged at the State Sanatorium. Not all the members are intelligent. Several are unusually stupid.

FIG. 2. View from roof of same house. Note abundance of light and air, and contrast the two pictures. On this roof the patient spent eighteen to twenty-one hours of the twenty-four.

dispensary treatment have been on the whole unsatisfactory is due to the lack of the careful supervision and the lack of the strict discipline maintained in sanatoria. The tuberculosis dispensaries have been a most potent factor in preventing the spread of the disease, and in educating the patients and the general public. But I believe relatively few cases treated by dispensary methods have been cured. This has certainly been the experience of my colleagues and myself in the out-patient department of the Massachusetts General Hospital, where the dispensary methods with the aid of the District Nursing Association have been employed for several years.

The difference between our method and that of the tuberculosis dispensary is essentially this: that the tuberculosis dispensary gives a small amount of care to a large number of patients, while we give a large amount of care to a small number of patients.

Our organization is known as the Emmanuel Church Tuberculosis Class. We sometimes speak of it as a home sanatorium, and it bears much the same relation to a sanatorium that a correspondence course does to a college course. Every detail of the daily life is supervised and strict discipline maintained. A nurse is employed who devotes her time to visiting the members of the class. I prefer the term "friendly visitor" to nurse, because it describes more exactly the nature of

FIG. 1. View from front of same house. Note lack of light and air, and contrast the two pictures. On this roof the patient spent eighteen to twenty-one hours of the twenty-four.

In the family of Zelek P., a Russian Jew, whose weight chart is shown, no one can write English, and his wife cannot speak English.

Before admission to the class, the patient is appointed a "friendly visitor" to a member of the class, and he is given the out-of-door life, and to observe the pro-

of the class. The truth of Brehmer's motto that "The most profitable work for a sick man is to get well," is impressed upon the patient. After the decision has been made to join the class a clinical history is taken and a complete physical examination made and entered on the clinical records. Once a month the lungs and sputum are re-examined. The patients are visited by the nurse as soon as they enter the class. Often before the decision has been made the nurse is sent to discuss the question with the invalid and his family and to determine whether it will be possible to carry out the open-air treatment in their home. If there be no roof, balcony, piazza, or yard available for the rest treatment in the open air, the family must move to a tenement that will enable the tuberculous invalid to spend the entire day and night out-of-doors. Our friendly visitor, Miss Strong, spent much time in seeking satisfactory tenements for our mem-

head out of the window of his bedroom. One of our class sleeps on a balcony, the others in tents placed either on the roof or on the ground near the house. Generally the tents have been loaned, as few of the members could afford to buy them. An ordinary 7' by 7' wall tent with a fly has been found satisfactory. This costs only \$7.25. Except the time taken for meals, bath and exercise, the entire day is spent in the recumbent or semi-recumbent posture. A comfortable reclining chair is furnished each patient.

The prescribed diet consists chiefly of milk, bread, fruit, butter and oil. Most of our patients drink two to three quarts of milk a day. In a few instances unsalted butter has been furnished free. Cotton-seed oil has been found to be a satisfactory and inexpensive substitute for olive oil.

For the first few weeks no exercise is allowed and later only when the temperature is normal the entire day. Then the exact amount of exercise is prescribed. The patient begins by walking five minutes in the morning and five in the afternoon. It is required that a watch be carried and the exact duration of the walk noted in his record book. After exercising the temperature is taken and recorded. If rise of temperature occurs or if the patient becomes tired the amount of exercise is diminished. If the patient continues to improve the exercise is gradually increased. Some of our patients now walk several hours daily. During the summer and fall our fever-free patients enjoyed the privileges of the Parker Hill Day Sanatorium.

An important aid in maintaining our strict hygienic regimen is furnished by the individual record book. The form of record adopted is that devised by Dr. Minor of Asheville. Every detail of the day is recorded: The food eaten, including the total amount of milk and oil taken; the number of hours out of doors; the temperature and pulse-rate, and the quantity and character of the expectoration. The patients now keep out-of-door life charts. This keeping of records serves to impress upon the members the importance of attention to detail in the treatment. It helps them to persevere in their monotonous life. We have found that it does not depress their spirits or cause introspection. It serves rather to keep up their courage. Most of the class take great pride in their records. Of course, if a patient were doing badly and losing weight rapidly, the individual record would be omitted.

A weekly meeting of the class has been held on Friday afternoons, formerly in my consulting room, now at the Massachusetts General Hospital. The record books are then inspected and the patient's weight, temperature, pulse and vital capacity are taken.

Expenses.—Emmanuel Church has paid for a special nurse, furnished tents, reclining chairs and all other necessary supplies. To a few of the members a small amount of money has been loaned and aid has been offered when it was necessary for a family to move to another tenement. A nominal fee of \$2.00 a month is re-

FIG. 4. Showing patient taking the rest treatment in her own yard. In the reclining chair she spends eight to ten hours daily.

bers. At the first visit the nurse examines the house and locality, obtains the social history of the case, ascertains the exact financial condition and gives whatever instruction may be necessary to prevent the spread of the disease. The first visit usually requires two hours or more. A detailed report of this is at once given to the physician in charge. Subsequent visits by the nurse are made as required. Usually the patient is visited daily or at short intervals, until the details of the treatment are understood and followed. It has been found that often repeated visits are necessary before some of the simplest rules can be fixed in the minds of the invalid and his friends.

On Jan. 5, 1905, the class numbered fifteen members, all but one of whom were sleeping out of doors. The single exception is a patient who would have done so had his landlord not prevented his putting a tent on the roof. At present he sleeps with his

quired from each patient. In some instances this has been remitted. The total expenses for the first six months ending Jan. 1, 1906, were \$513.00.

Miss Isabel Strong, acting as friendly visitor, gave her entire time to the work without pay during July and August. Dr. J. B. Hawes has assisted me in the medical work since the organization of the class. Recently Dr. C. S. Millet and Dr. N. K. Wood have associated themselves with us and Dr. G. L. Tobey has taken charge of the laryngological work.

Tuberculin has been used in a number of cases with apparent benefit. Pharmacotherapy has rarely been employed except for special conditions, such as constipation or diarrhea. In a few instances creosote and compound tincture of gentian have been used. Hydrotherapeutic procedures consisting chiefly of "Theilwaschungen," Priesnitz chest compresses and full-tub baths have been prescribed in every case.

Results. Of the nine patients who have been members of the class for three months or more, all but one show a gain in weight. One patient's weight has increased 39½ lbs. In five of the nine cases the disease has been arrested. The term "arrested" is used in the sense in which it is employed by the Committee on Nomenclature of the National Association for Study and Prevention of Tuberculosis in their classification.

WEIGHT TABLE OF ALL WHO HAVE BEEN MEMBERS OF THE CLASS FOR THREE MONTHS OR MORE.

| Name | Date of Admission | Wt. at Admission | Last examination | Wt. at examination | Gain | No. of Weeks |
|-------------------------|-------------------|------------------|------------------|--------------------|----------|--------------|
| 1. Minnie E., | July 3 1904 | 102½ | Jan. 12 1905 | 111½ | 11½ lbs. | 27 |
| 2. Elmer C., | " 12 1904 | 106 | " 5 1905 | 130½ | 24½ | 25 |

| Average gain 19 10 lbs. | | | | | | |

ABSTRACTS OF THE CLINICAL RECORDS OF ALL WHO HAVE BEEN MEMBERS OF THE CLASS THREE MONTHS OR OVER.

CASE No. 1. Minnie E., aged twenty-eight. Housekeeper. Ill since May, 1901. Cough; night sweats; loss of weight and strength; loss of appetite; frequent vomiting. Went to the Massachusetts General Hospital in January, 1905. Weight then 106½ lbs. Tubercle bacilli present in sputum. Joined the class July 3. Temperature at time of the first examination 98.8, pulse 100, respirations 26, weight 102½. There was dullness at the right apex, bronchovesicular breathing and many fine, moist râles. At the right base crackles were heard. In the left interseapular region slight dullness, bronchial breathing and râles at the end of expiration. Jan. 12, 1906. Weight 111½ lbs., temperature 98.6, pulse 84. She now feels strong and complains only of occasional nausea and vomiting. Practically no cough and no expectoration. No fever for four months. Last examination of chest Jan. 9. Only a few râles are now heard and these are sticky in character. They are present at both apices. On Dec. 22 sputum contained tubercle bacilli. Gaffky seed No. 2.

CASE No. 2. Elmer C., aged fifty-six. Painter. Came to Dr. Pratt's clinic at the Massachusetts Gen-

eral Hospital in July, 1905, complaining of loss of appetite and pains in the chest. He had had a dry cough for five years and expectorated some blood one year ago. For the week previous to visiting the hospital he had been troubled with night sweats. There had been no noticeable loss of weight; slight loss of strength. *Status præsens:* Thin man, bony framework prominent; weight 106 lbs. Temperature 99.6, respirations 18, pulse 92. Mucous membranes somewhat pale. Chest rather long and narrow. Dullness

OUTDOOR LIFE CHART.

Name *Elmer C.* No. *3.*
Locality *Essex*
Date *August 1905*

An outdoor life chart selected at random. It shows that Elmer C. was out of doors on no day of the month less than nineteen hours.

over the left upper lobe in front, and flatness behind. Over both sides of chest above spine of scapula breathing is bronchovesicular with prolonged expiration. Kroenig's isthmus is 2 cm. wide at the left apex and 3 cm. at right apex. Vital capacity is 2,225 c.c. Many medium-sized moist râles over both upper lobes during both inspiration and expiration, more numerous on left side, no râles over middle or lower right lobe. Over lower half of left scapula, especially near angle of scapula are a few crackles. S. lowered and anterior tortuous brachials. Trachea is free from dullness and sugar. Suggestion of diaphragm reaction. Sputum is mucopurulent. Tubercle bacilli present. Gaffky's seed, No. 3. Fluoroscope shows a shadow over the entire left lung darkest at the apex. Right lung clear. He regained strength rapidly and the cough entirely disappeared. Tubercle bacilli have not been found in the sputum for three months. Jan. 9. Patient looks healthy, skin ruddy, and mucous membranes are of good color. Weight 104½ lbs. Temperature 98.8, pulse 78, vital capacity 2,500 c.c. He has lost less than he has for years and weighs 100 lbs. more than he did when he came to the clinic. He walks four to five hours daily. Last examination of chest Jan. 14, 1906. Mucous membranes of chest and apex. No impairment of respiratory function of either lung. At left apex expiration is prolonged and flat

distinctly bronchovesicular. After coughing, a few subcrepitant râles were audible above the left clavicle; none were heard elsewhere.

CASE NO. 3. Zelek P., aged thirty-five. Tailor. Came to Dr. Pratt's clinic at the Massachusetts General Hospital in July, 1905, complaining of cough and pain in the right chest. For several months he had been troubled with a cough and increasing weakness. He had lost 3 lbs. in weight since January. On examination he was found to have a temperature of 101.4, respirations were 30 to the minute and the pulse 80. There was dullness over the right side of chest, front and back, shading into flatness at apex. Breath sounds were bronchovesicular over right upper lobe, where a few fine râles were heard. They were increased by coughing. Sputum contained many tubercle bacilli. — Gaffky scale, No. 7. He gained steadily

had a cough with considerable expectoration for three months; at times sputum had been streaked with blood. He had not lost weight; his appetite was good, and aside from the cough felt perfectly well. There were slight signs at the right apex, and the fluoroscope showed a shadow extending down as far as the third rib on the right side. There was a reaction to tuberculin and then for the first time Dr. Hawes found tubercle bacilli in the sputum. Examination, Jan. 2, 1906, revealed slight dullness and bronchovesicular breathing at the right apex. No râles were heard. He looked strong and healthy. Has had no cough for two months or more, and tubercle bacilli have not been found in his sputum since September. On Jan. 12, he weighed 153½ lbs., a gain of 22 lbs. since joining the class. His temperature was 98.4°, and his pulse 104, vital capacity 3,000 cc.

Weight Chart

Name Zelek P.

Weight chart of the member of the class who lived on the roof shown in Fig. 2. On Jan. 19, 1906, he weighed 171½, being a gain of 40½ pounds. He now walks three hours daily without fatigue.

during the summer and fall. He slept and lived on his roof in the crowded West End of Boston. For ten weeks he was allowed no exercise. His temperature became normal in September, and has remained so. On Jan. 12, 1906, he weighed 171 lbs., temperature was 98 and pulse 82. He has been free from all subjective symptoms for several months, but in the scanty expectoration tubercle bacilli are still demonstrable. Examination, Dec. 30, showed dullness, bronchial breathing and intense bronchophony at the right apex in front. A few râles were heard here, none elsewhere.

CASE NO. 4. John H., aged twenty-two. Brass finisher. Came to the clinic in July, 1905. He had

CASE NO. 5. Samuel T., aged thirty-seven. Motor-man. Cough of six months' duration. One attack of hemoptysis. A few night sweats. Lost 70 lbs. in weight during the past two years. Definite signs of phthisis were found at the right apex, and the sputum was loaded with tubercle bacilli. At the time of examination, July 27, 1905, his weight was 142 lbs., temperature 98.2° and pulse 116. Improvement followed treatment. He remained in the class six weeks and gained 14½ lbs. He then returned to his old home in New Hampshire, where he remained a month. While there he over-exerted himself and the tuberculous process was lighted up. He rejoined the class on Oct. 27. He was then having afternoon

ferred to the Emmanuel Church Tuberculosis Class by Dr. Cabot in September. Pleurisy, January, 1905. Slight hemoptysis also in January. In July, 1905, cough began. Occasional night sweats, some pain in chest. He had lost about 20 lbs. in weight and felt weak and sick. Weight 145 lbs., temperature 101.5°, pulse 104. There were signs at the right apex and tubercle bacilli were found in the sputum. He has improved steadily under treatment. On Jan. 2, 1906, slight dullness at right apex; no definite rales heard. Jan. 12, weight 166½ lbs., temperature 98°, pulse 104. Slight cough persists; general condition good. Sputum examined on Dec. 22 contained numerous tubercle bacilli.

CASE NO. 9. Patrick C., aged thirty-three. Machinist. Came to Dr. Cabot's clinic at the Massachusetts General Hospital in August, complaining of shortness of breath. He had had a persistent cough since last winter. While in New York in June, 1905, he was suddenly seized with great shortness of breath, high fever and prostration. He has been quite sick ever since. Patient was emaciated. On examination there was found to be a pyopneumothorax of the left side and signs of phthisis at the right apex. Weight was 117, temperature 100.5°, pulse 84. An incision was made in the left side and considerable pus removed which contained tubercle bacilli. In September he was admitted into the Emmanuel Church Tuberculosis Class. On Oct. 13, 450 cc. greenish pus were removed, which greatly relieved the dyspnea. Temperature 100°, pulse 108. On Oct. 27, 1,080 cc. of fluid were aspirated and again on Dec. 19, 500 cc. were removed. He has continued to have slight fever. The physical signs have remained nearly stationary, but he has been weak and has had very little appetite. Jan. 12, 1906. His lips look bloodless. Left side of chest remains distended and flat. Weight 124 lbs., temperature 98.6°, pulse 92, vital capacity 1,100 cc.

COLD FRESH AIR TREATMENT OF PNEUMONIA. A CASE.*

BY W. P. NORTHRUP, M.D., NEW YORK.

Professor of Pediatrics in the University and Bellevue Hospital Medical College; Visiting Physician to Presbyterian and Foundling Hospitals, New York.

THERE are two reasons for the appearance of this report. *First*, it makes a favorable showing for fresh air treatment in a prolonged case of severe pneumonia. *Second*, we are privileged to learn how the treatment impresses the onlooker.

In this case the onlooker was an up-to-date oculist, a back-number general practitioner, a father who really thought this particular young boy was a little different from others. The said onlooker has been for years active in this society, and all who fear their patients will not consent to this radical change in treatment may wish to ask him questions. He is here and will answer.

History: F. V. F., thirteen years old, finished a bicycle ride without incident, without exposure or excessive fatigue. On the following day he came from school, having felt "bad" during session. At noon, however, he ate a good lunch with his father, and seemed perfectly well. In the afternoon of this day there was an abrupt onset of the following symptoms: malaise, persistent vomiting, severe headache. The throat was red, and no other local indications. The toxemia and nervous disturbances seemed marked,

but in a nervous boy of thirteen not exceptional. On the morrow, it was predicted, he would probably show tonsillitis.

On the second day no improvement, no diagnosis.

Third day: During the night the fever mounted, and in the morning all the symptoms needed for diagnosis were present. There was a temperature of 105°. Respiration-pulse ratio, 1 to 3, pain in the chest, nausea, transient delirium, restlessness, cough.

Character of the pneumonia: Clinically it was of grip type, wandering, prolonged, resolving without sputum. It began in the left lower, spreading gradually to the root, advanced to the upper posterior, then to the apex, spreading around in front. In short, it involved the entire left side.

The initial point of lesion was so attended with pleurisy and so solidly flat that empyema was expected, and when the fever, after a short decline, mounted again to maximum, the instruments were boiled for exploration. While they were boiling an examination disclosed the fact that the consolidation was clearing from below upwards, and that a new district was invaded in the upper lobe posteriorly. After a slight decline of fever again it was hoped that having seemingly invaded every portion of the left lung and taken twelve days to do it, there was about to be an end of extension and mental suspense. Alas, another sharp rise of temperature made certain interested persons look despondent. It was a question whether the process had now jumped to the other side. It had not. The spreading infecting agent had seemingly overlooked or forgotten one little place near the sternoclavicular articulation, to which it now, on the twelfth day, returned and incited the known cycle of pneumonic activity. It was attended with characteristic physical signs. The temperature again declined. By this time the tension of mind of the family may be easily imagined.

From the extent and character of the consolidation alone this is not to be considered a mild case. The fact is here dwelt upon for a purpose. Certain symptoms serve to further mark its severity. Among them are restlessness, nausea and vomiting, delirium described as muttering, or active, nearly all the time for twelve days, talking incessantly. Delirium was often violent, with fighting and attempts to escape from bed. Further symptoms were dry tongue, moaning in sleep, picking the bed clothes, risus sardonius, respiration irregular, pulse irregular, at times dirotic, face flushed, abdomen distended.

The temperature touched 104°-105° every day for nine days, fell a little from the tenth to the eleventh, mounted again on the twelfth, and remained normal after the thirteenth.

The respiration averaged 35 to 40, by exception reached 50 and more. The pulse was seldom above 120 and usually of good character. This was a great source of comfort. Truly the heart behaved well.

After a moderate internal sensation in one ear on moving his jaw, the ear began to discharge. This made an uneventful recovery, and did not seem to influence the temperature.

The foregoing description, it is hoped, serves to determine the gravity of the case. No difference of opinion exists as to the depressing and exhausting effects of this type of pneumonia.

After condition: The patient recovered his appetite, his ability to sleep and go about the city, and was, to physical examination, quite well, lungs and ear, but not psychically. Delusions pursued him. Impressions previously acquired from

* Read before the New York County Medical Society, Jan. 22, 1906.

highly pictured stories came to his mind. In the bathroom's dark corners he saw queer objects. He prowled about the house in fear lest he should be surprised by lurking somethings. He shunned his old friends, his teachers and playmates and turned his face to the wall if they came suddenly upon him. It was fully three months before this wore off. During all this time he was well enough to walk in the park, and was eating and sleeping satisfactorily.

His condition reminded one of the post-typhoidal mental state associated with exhaustion, malnutrition of the cells and anemia. He had illusions, delusions, dysesthesia, a grinning, vacant look, nocturnal enuresis, anemia.

I may here happily remark that this fall a bright youngster with a gay dog in leash dashed up to me on the street, in a way that assured me that the former patient was as fine and fit as ever. He is now perfectly well, and I can believe the father still thinks him exceptional. Ask him.

Treatment.—From the first it was apparent that the patient was going to be very sick. He was a tall, thin boy, growing rapidly, and looked to the casual observer rather delicate. There is always a little embarrassment in attending the son of an old friend doctor. However, I must admit it was reduced to a minimum in the present case.

The bed's head was placed between two open sashes in a bay-window. The lower sashes were opened to their utmost, and the month was March (1905). On account of active delirium it was necessary to pass a cotton flannel bandage around one ankle and fasten it in a long loop to the iron bedstead. At times other precautions were necessary. The approved method of treatment required the windows to be wide open and quite unobstructed. The working rule was, Nothing between the nose and the North Pole.

The room was cold, perhaps 10° Fahr. The nurses wore heavy wraps, night and day. No one caught cold and before the end all fully approved the method of treatment.

The boy wore no oilskin jacket, had no extra cover over his chest, his arms were out. In fact, before the end of the first week, he was allowed to tear open his shirt at the throat, expose his upper chest or anything he wished to further his comfort. To him who shudders at this treatment, let me say, the father, whatever he thought, made no objection. If he and his wife filled with inherited traditions concerning blankets, windows and poultices, were convinced that the cold air on the boy's face, hands and chest not only did him no harm, but gave him comfort and quieted him, there is hope for others. Let the hearer and reader remember that this young boy was sicken with poison. He was overheated, prostrated, doped. The fresh air streamed into his face, moved the hair on his forehead, it passed in at one window over his head and out another window. It was the best March air to be had in New York.

Hot, dry skin, dry tongue, muttering delirium; limited lung capacity, call loudly for two aids—

water and air. The heart, blood and kidneys need them. A person looking on that boy, even though a parent and lay member, could be easily convinced that a hot constricting poultice and vitiated air were not indicated. These would possibly have killed him.

The present case is not placed before this audience because all here present do not give air and water to some toxic patients, but because there are some who still do not give it to pneumonia patients.

Drink and draught were once denied the fever-stricken. Now one prescribes both. Once it was a conscientious duty to withstand the piteous appeals for water, likewise to blanket the windows. The parched tongue might swell and cleave, hot hands reach out in vain; water and air must not be given. A young soldier from the Berkshire Hills made a southern fever hospital ring with his delirious cries for a long drink from his father's well. Who but such as he can understand the meaning of the cool touch of fresh currents of air?

Finally: Some one present may wish to say what one person has said to me concerning another case: "It's fortunate that child got well, or you'd have been mobbed." Not so. The parents, under the influence of much explanation and the observation of the case, were convinced that the treatment fitted the indications.

The time has come for thinking. The time has come to give fresh, cool, flowing air and fresh cool draughts of water to the stricken, fevered child. 'Tis time to cool and dilute his blood stream, aid it to unload its toxic material, to drain it from the system. 'Tis time to lightly lend a hand to steady the nervous regulator, to cool and bathe, soothe and refresh. Who now would shut typhus in a close ward? Refuse a drink to burning scarlet fever? Who would, now that they have thought of it rationally, refuse fresh air to a pneumonia patient sodden with toxemia? They cannot catch cold while the fever is on. They are more comfortable, bear their disease better, emerge from the campaign less damaged, recover earlier and more perfectly. There are no dangers, there are all advantages.

New Instrument.

A NEW GOUGE FOR SUBCUTANEOUS OPERATIONS IN THE NOSE.

BY HOWARD A. COHEN, M. D., F. R. C. S.,
Assistant Lecturer in the History of Medicine, University of London, and Lecturer in the History of Medicine, University of London.

At the present time while there is much interest manifested by the medical profession in subcutaneous operations in the nose, the author wishes to describe here a subcutaneous gouge which has been found useful in removing cartilage and bony thickenings of the septum.

The accompanying cut gives a general outline of the description of instrument (See Fig. 2).

Length of the entire instrument is five inches; guard (a), three eighths of an inch; length of sharpened edge (b), five sixteenths of an inch; breadth, five sixteenths of an inch. The guard overlaps the cutting edge by a little more than one sixteenth of an inch. The guard of the gouge is blunt and its edge well rounded, thus making it impossible to injure the mucous membrane. The instrument was originally designed to reduce flat anterior cartilaginous thickenings for which the drill or cautery was used. The writer has found it useful in removing bony thickenings of the vomer.

By doing as little injury as possible to the mucous membrane we avoid the very annoying crusting which follows the use of the cautery, saw or burr.

In doing any of the various "window operations" one is often confronted with a marked thickening at the most prominent part of the convexity, and in these cases the operation is much facilitated by first using the gouge. It not infrequently happens that sufficient air space can be obtained by this alone. The only blood vessels of any consequence cut in this method of removing thickenings are those severed during the first incision, consequently there is very little hemorrhage.

Description of the operation in detail: Local anesthesia of the operative field is first produced by rubbing in thoroughly a 10% solution of cocaine with a cotton swab and in the same way we rub in a 1-3000 adrenalin solution.

Next, the nose is thoroughly irrigated with "alphozone" solution, 1-2000, or corrosive sublimate solution, 1-10000. A straight or slightly curved perpendicular incision is made through the mucous membrane and perichondrium as low on the projecting cartilage as the operator wishes to remove the section. The periosteum elevator is then inserted under the perichondrium and gradually worked backward to about one fourth of an inch beyond the thickening and somewhat above and below the piece of cartilage the operator wishes to remove.

The guard is now inserted under the mucous membrane and perichondrium and the sharp edge of the gouge is engaged in the part to be removed. If the portion to be removed consists of cartilage alone the gouge is very easily pushed through, but where there is bone it sometimes requires a slight blow of the mallet to sever it completely.

Care should be taken that enough bone and cartilage be removed and that no projecting bits are left to hold the mucous membrane away from the septum. After the section is removed the cavity is irrigated with a disinfecting solution and the two edges are connected and a stitch taken if necessary, but the writer has never found it called for. A piece of antiseptic cotton is pushed well into the nose and then drawn forward, this brings the two edges together and at the same time brings the perichondrium in contact with the septum.

In a number of cases there has been good union in about twenty-four hours. After the cotton is removed the patient is given an antiseptic spray to use at home four times a day. When the incision can be easily reached with the finger the patient is given mild citrine ointment to apply night and morning. The operation can be done in from three to eight minutes. In cut No. 1 the dark line shows the thickenings before the cartilage was reduced with the gouge, while the dotted line shows the line of the septum after its removal. If it is necessary at any time to remove the mucous membrane with the cartilage it can be done more expeditiously and with less shock to the patient with the gouge than with the saw.

The writer has found the instrument very satisfactory in removing turbinates where the bone is enlarged, and it is also much safer for the general practitioner who has seldom an occasion to use such an instrument.

FIG. 2.

While the dimensions of the largest size gouge only are here given it is well to have at least two smaller.

The advantages claimed for this instrument are:

- (1) The rapidity with which one can remove thickenings under the mucous membrane.
- (2) Safety.
- (3) Rapid healing with little or no crusting.
- (4) Ease with which one can remove broad, flat thickenings which could not be engaged with the saw.

The above instrument was made for the writer by Codman & Shurtleff of Boston.

Reports of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

STATED MEETING, WEDNESDAY, JAN. 10, 1906.

The president, DR. JAMES M. ANDERS, in the chair.

CHRONIC ACETANILID POISONING, WITH REPORT OF A CASE DUE TO ABSORPTION OF THE DRUG FROM AN ULCER OF THE LEG.

DR. JAMES R. HERRICK of Chicago read a paper reporting this case. A woman of fifty for seven years applied daily to a large varicose ulcer of the leg about an ounce of a powder the nature of which was unknown to her. There had been weakness, dyspnea, palpitation, mental depression and general "nervousness." Cardiac and pulmonary findings did not explain cyanosis which was present. The powder was found to be pure acetanilid. Stopping its application there is complaint of pain and extreme restlessness with almost maniacal excitement. The reapplication of the powder or the use of acetanilid from the drug room internally quieted the nervous systems. By gradual lessening of the amount of the drug applied it was finally given up. This was followed by improvement in the general condition. The study of the case for several weeks showed that the effect of the chronic intoxication on the general nutrition was marked. Anorexia, irregular action of the bowels, weakness, with considerable emaciation disappeared promptly when the drug was stopped. The blood did not show methemoglobinemia as reported in some other cases. The anemia was moderately severe. Leukocytosis was moderate. Morphological degenerative changes in the red corpuscles were not pronounced. One month after the use of the acetanilid was then stopped the blood count showed 5,580,000 red corpuscles and 100% of hemoglobin. The urine averaged 1,800 cc. with a specific gravity of 1.015. It was port wine color and on standing became brownish black. Fehling's solution revealed no copper reducing substances. The enlargement of the spleen was striking, as was its distinct diminution in size when the intoxication was at an end. Feeding acetanilid to animals failed to produce splenic enlargement, except in one dog, where a slight enlargement with connective tissue increase was found. The addition to the use of the drug was as pronounced as in the case of the morphine or cocaine habit *à*, though more amenable to treatment, which was here entirely successful by the method of gradual withdrawal.

Dr. Herrick thought the acetanilid habit probably more common than generally supposed. The case with which the drug may be obtained by the laity either in its pure condition as the main ingredient of patent and proprietary medicines sold for the relief of headache tended to this frequency. The recognition of the condition depended on the detection of the use of the drug. Otherwise unaccountable cyanosis should arouse suspicion. Alimentary disturbances and neurotic symptoms may be due to the poisoning. The enlargement of the spleen has been reported in several cases. Secondary anemia may be extreme. Strangely enough, in some cases polycythemia rather than anemia has been reported. One such case in a chronic intoxication from the prolonged use of orange has been under Dr. Herrick's care. The shrewd and to diagnosis was said to be the examination of the urine which reveals the dark color, paramidophenol and increase in the conjugate sulphates.

It was pointed out that the condition must be differentiated from diseases that might produce cyanosis, such as cardiac and pulmonary disease, as well as from

the anemias and leukemias. Careful study of the blood, it was said, would clear up these differential points. Cyanosis with polycythemia and splenic enlargement may be simulated by acetanilid intoxication, as may cyanosis that is enterogenic. The study of the urine is here all important as an aid to diagnosis.

The author said that promising fields for investigation were opened up by the recent interest in cases of cyanosis, polycythemia and splenomegaly. He suggested that perhaps a study of chronic acetanilid poisoning might throw some light upon these cases.

DR. ALFRED STENGEL spoke of the necessity of distinguishing between acute acetanilid poisoning, which is exceedingly common, and chronic acetanilid poisoning, which is rare. His experience is limited to five cases, three of which he had examined, two others he had seen but was not permitted to report. The first case was one similar to that reported by Dr. Herrick. There were the marked changes in the blood such as he had not seen in any other case, the very marked change in the character of the red corpuscles with the very decided tendency to nucleated red corpuscles. The case was that of a young girl brought to the University Hospital to be under the care of Dr. Matthew H. Cryer for tritaneal neuralgia. Upon her arrival from Connecticut she was in such a desperate condition that surgical treatment was not warranted and she was put under medical inspection. She was extremely cyanotic. By direction of Dr. Stengel she was bled to the extent of six or eight ounces. Dr. C. Y. White was convinced of the presence of acetanilid poisoning and soon convinced Dr. Stengel of the truth of his theory. After investigation it was found that the girl was surreptitiously receiving acetanilid capsules and the patient afterward confessed. The case was one of those diagnosed as congenital heart disease. The diagnosis had been made by a distinguished clinician who, it was suggested, was a good deal occupied and had made a more or less casual examination. Among several other diagnoses which had been made of the girl's condition was that of mediastinal tumor. That such mistaken diagnoses should have been made was not a surprise owing to the most remarkable changes through which the heart passed. It increased tremendously in size. She had had several attacks of acute dilatation with the appearance and subsequent disappearance of a loud systolic murmur with corresponding increase and subsidence in the intercostal cyanosis. With the intercostal cyanosis the extremities were warm. This was one of the first features suggesting the true nature of the case. Dr. Stengel expressed his belief that such changes in the heart could not be produced without serious damage to the musculature. To have a heart suddenly dilate and spread an inch or an inch and a half, beyond period of ventricle of a doubt, and then pull itself together again, the cessation of the drug, and the cyanosis disappear, he felt could not but leave some impression upon the heart. Interesting features were presented at the two other cases he had examined. In one, that of a very intelligent man, there were symptoms of cyanosis of the fingers and lips, with a sort of steel blue color of the skin. The man had been taking Phenagan, and showed what Dr. Herrick had called a "phenaginic perversion." When under the influence of the drug he ceased taking it, when at under its influence he was willing to confess his use of it. The other case was that of a woman who secured the drug without the physician's knowledge. Dr. Stengel's diagnosis was proven to be correct. While under the influence of the drug it was possible to induce cyanosis which disappeared when the drug was stopped.

In the first case of the series cyanosis, intercostal cyanosis, greatly enlarged heart, steel blue color of the skin,

enlargement but marked polycythemia. This had suggested the possibility of some of the cases reported of chronic cyanosis being those of acetanilid poisoning, which would explain the polycythemia. In the two latter cases there was no change in the character of the red corpuscles.

Aside from these intense cases, Dr. Stengel believes with Dr. Herrick in the existence of a large number of cases of acetanilid poisoning of minor grade. In his own practice he has seen cases of disturbance of heart action and of general health which he believed due to frequent ingestion of the drug in sufficient amounts to interfere with health. Because these are the cases most numerous he believed them of the most importance to the profession. Here again he believed with Dr. Herrick that if physicians were on the alert the cases would not be difficult to recognize. He admitted the possibility of their being mistaken for a number of conditions as detailed by Dr. Herrick.

DR. S. SOLIS COHEN continued the thought expressed by Dr. Stengel that the physician should be constantly on the watch for the minor grades of acetanilid poisoning. In cases presenting ill-assorted and vague symptoms, explanations other than the true one might be given, unless some knowledge of the history or unguarded remark of the patient directed attention into the right channel. He recalled the case of a very intelligent man who had been under his care for a number of years, who had originally had attacks of migraine which he had himself treated by tablets bought at any drug store. These headaches and attacks of vomiting had been completely relieved by the use of glasses prescribed by Dr. George M. Gould. This case was an instance of true migraine relieved by proper refraction, the existence of which was looked upon with doubt by a good many neurologists. Some time after passing from under Dr. Cohen's observation and while spending the summer in the mountains he was suddenly attacked with fainting, and he was informed by the examining physician that he had acute Bright's disease. He returned promptly to Philadelphia. Dr. Cohen's examination of the urine discovered the urine to be free from albumin, casts and sugar. It was learned that the man had been taking, when he felt tired, some bromo-seltzer. A further study of the case convinced Dr. Cohen that it was one of chronic acetanilid poisoning. In another case recalled by Dr. Cohen in which the patient had had chronic heart disease for some time, the cyanosis was out of proportion to the cardiac lesion and investigation showed the bromo-seltzer habit. He is convinced that bromo-seltzer is, perhaps, the most common and most dangerous cause of chronic acetanilid poisoning among intelligent people.

One of the great dangers of chronic poisoning with coal tar products was pointed out to be the sudden yielding of the heart to some unusual strain. Dr. Cohen further recalled the case of a young woman who had persisted in the taking of some coal tar product which had been originally prescribed for migraine. About a year after her marriage she died suddenly following an apparently normal labor. The knowledge of the continued use of the prescription during pregnancy gave the clue to the cause of death. The cases were cited as illustrations of the widespread habit of taking coal tar products and of the hold which the habit takes upon people although warned against it. He pointed out the importance of recognizing the early changes resulting, and the importance also of not mistaking for serious organic disease of heart or kidneys, the profound cyanosis sometimes developed.

DR. HENRY LEFFMANN called attention to the probability that under the condition of the new Pharma-

cepeia there would be an increase in the cases of chronic acetanilid poisoning. This was because the Pharmacepeia had put upon its list the compound powder of acetanilid which was expected to take the place of the commercial compounds. He thought the motive had been to meet the existing situation, in itself undesirable. In his opinion it was bad judgment to so place it, since every pharmacist would feel at liberty to sell it for headaches. A few of the high-class pharmacists would sell phenacetin, but with the cheaper price of acetanilid the tendency would be to sell the latter. He recalled the statement of an English physician that many so-called rare diseases were possibly only exaggerated forms of common conditions, and that if physicians would learn to look for the marked symptoms they would find the disease to be far less common than supposed to be. He believed that the practice of taking these drugs was so excessive and so encouraged by prescribing druggists that many troubles were mistaken by physicians for conditions of real disease, whereas, they were really conditions of acetanilid or other coal tar products poisoning.

DR. H. C. WOOD, JR., thought that Dr. Herrick had made out a very good case of the non-existence of chronic acetanilid poisoning. It had seemed to him that Dr. Herrick's case, also that of Dr. Stengel, were those rather of a series of successive acute poisonings than of one chronic poisoning. There were not shown any of the characteristic symptoms following chronic poisoning; for example, as in sulfonal, the persistence of the symptoms after the withdrawal of the drug, and no permanent injury wrought by the prolonged use of the drug. Moreover, it was voted that Dr. Herrick in his experiments had been unable to produce any serious pathological lesion in animals by the prolonged use of the drug. The symptoms had occurred immediately following the administration of very large doses of the drug, and persisted, because the drug was persisted in until the animal died. It seemed to him, therefore, much more logical to regard the cases as repeated attacks of acute poisoning following the repeated ingestion of the poison.

This, of course, had no bearing upon the existence of the drug habit. He thought there was a distinction to be made between the existence of the drug habit and the existence of poisoning produced by that habit. A point of interest to him was the suggestion that the cyanosis had occurred as the result of the ingestion of acetanilid. He thought it was commonly held that cyanosis is due to the presence of methemoglobin in the blood. Dr. Herrick and others, however, had failed to find any methemoglobin in the blood. If this were present in small quantities its existence might be difficult to prove. On the other hand, if present in only small quantity, it could not account for the marked degree of cyanosis in these cases. He, therefore, thought that the large degree of cyanosis must be ascribed to the acute dilatation of the heart and failure of circulation characteristic of poisoning by the drug. It had been shown by Sanger that blood which has undergone chemical change with production of methemoglobin is not destroyed; that is, it is possible to restore hemoglobin to a corpuscle which has had its change of methemoglobin. The experiments of a German investigator have shown that in those cases in which the blood has undergone chemical change, a larger proportion of oxygen will be taken up, if the atmosphere is one of pure oxygen. He experimented with mice and found that in an atmosphere of pure oxygen they would withstand a dosage two or three times as large as a fatal dose. He also found that if he increased the pressure of the oxygen they would withstand a still larger dosage of the poison.

Dr. W. M. L. COPLIN had not seen a case of chronic acetanilid poisoning and had had little experience with the acute forms. He referred to researches made under his direction upon the influence of the coal tar products upon the protoplasm of the red blood cells. The work was especially in connection with the aniline dyes, antifebrine and antipyrine. Such marked changes in the red blood cells were found that on the cover glass the blood lacked the color of ordinary blood. A point of diagnostic value mentioned was the appearance of the exudates when present. Nothing was found characteristic of actual nephritis. In concurrent work done with carbolic acid renal changes were quite marked. From Dr. Coplin's work upon the spleen of animals he regards with some skepticism reported instances of cirrhosis of the liver. One experimenter, in a large number of dogs, had observed a single case of cirrhosis of the liver. Concerning the microchemical reaction of the blood the research work did not prove satisfactorily that there was any morphological change in the blood which was at all characteristic. The striking feature was that there was no change in the stringibility of the blood explaining this peculiar hue of the freshly dried blood.

Dr. JAMES C. WILSON said that if the distinction suggested by Dr. Wood between repeated acute attacks and chronic acetanilid poisoning were to be observed, cases of the latter were indeed very limited. He cited his observation of a case showing the occurrence of a persistent symptom in a patient by whom large doses of acetanilid were taken every day. The patient, a man of about twenty-six under treatment for a couple of years for syphilis, had taken enormous doses of the iodides. He had suffered much from headache and there was noted progressive tendency to cyanosis which his attending physician tried to explain by some idiosyncrasy to the iodides. Coming under Dr. Wilson's care in the hospital the character of the cyanosis and the cardiac symptoms with splenic enlargement led to the diagnosis of acetanilid poisoning. Investigation showed that the patient had had, prior to the chancre, migraine, and had formed the habit of taking different kinds of headache powders obtained from the apothecary. During the treatment for syphilis he had taken "Orangeine" powders, never less than six or eight, sometimes as many as 18 or 20. Attempts to withdraw the drug were followed by outbreaks of intense headache. With the substitution of small doses of morphia without the knowledge of the patient all the symptoms disappeared and he left the hospital without having taken either acetanilid or morphia for two or three weeks and without the knowledge that he had had morphia. The point made by Dr. Wilson was that brought out by Dr. Herrick that in some of these cases the original cause of distress may disappear and be replaced by a similar continuous suffering arising from the use of the drug itself. In Dr. Wilson's case the ultimate withdrawal of the acetanilid was followed by complete cessation of the headache for which the patient had habituated himself to the drug.

Dr. DAVID L. LORRAIE said that he had had little experience with chronic acetanilid poisoning. He inquired of Dr. Herrick how much evidence was shown by the literature of the persistence of mental symptoms after chronic acetanilid poisoning of long duration. He had seen one case, whether coincident or otherwise, in which the man had developed chronic mental symptoms and had been placed in an asylum for the insane.

In regard to the relation of the methemoglobin to the symptoms, in one case in which there was profound cyanosis, examination of the blood and urine revealed nothing but oxyhemoglobin in the blood and in the urine and no methemoglobin. He said it was certain

that the presence of methemoglobin was not a satisfactory explanation of the cyanosis. Reference was made to one authority on the chemical analysis of the urine who had cast much doubt upon the existence of methemoglobinuria and considered the vast majority of the reported cases due to erroneous observation. Dr. Edsall thought the same might be true of the blood.

Dr. W. E. ROBERTSON said that his experience had been limited to two cases, — one an acute case in which the infection occurred from an acetanilid dressing and in which the symptoms subsided upon the withdrawal of the dressing; the other, a chronic case, and in this the blood picture was similar to that presented in the discussion. In the chronic case, notwithstanding the great cyanosis, there was no dyspnea. It resembled very much a marked case of polycythemia in which the cyanosis is of intense degree.

In connection with Dr. Wood's reference to the cases being regarded as instances of repeated attacks of acute poisoning rather than of chronic poisoning, he cited one observer who had noted upon the complete withdrawal of the drug the persistence of the symptoms and also of mental symptoms.

Dr. GUY HINSDALE said that in the early days of the use of acetanilid when it was known by the name of antifebrine he thought the drug was used much more freely and injudiciously than at present. He recalled the case of a young man with epilepsy in whose treatment the remedy was used for two years, and this patient upon leaving the city for a year had obtained a considerable amount to be used continuously. Upon his return while there was some cyanosis no other bad effects were apparent. The effect upon the epilepsy was not curative, but probably mitigating. At the present Dr. Hinsdale would hesitate to use the drug in the quantities in which it was formerly employed.

Dr. HERRICK, in closing, was inclined to regard the criticism of Dr. Wood of the term "chronic" acetanilid poisoning as a just one. He thinks that probably the action in these cases should be looked upon as cumulative; and yet, he does not believe that it has been definitely decided how permanent the damage done is. It cannot be stated certainly that the heart muscle was not more or less permanently damaged, nor that the blood making organs would be restored to their normal function. Neither was there certainty concerning permanent mental effects. He replied to Dr. Edsall that he could not answer his question regarding permanent mental derangement following chronic acetanilid intoxication. Most of the cases had recovered quite promptly upon the withdrawal of the drug. From the records of some of the cases he had observed that the finding of methemoglobin was somewhat doubtful, and felt that the examination for its presence should be very carefully conducted before it was declared to exist.

Dr. HERRICK inquired whether any of the members present had ever seen a case of chronic nitroing poisoning. He had within the last few weeks seen a patient with a history almost identically that of the cases under discussion. The cyanosis was most intense and could not be accounted for by any discernible cardiac or pulmonary lesion. The patient, a German woman of advanced years, had been taking half a tablet daily for fifteen years for some bowel trouble. Also at a week before she was seen by Dr. Herrick she had stopped the nitroing. Nothing abnormal was found in the urine and the cyanosis, though extremely, was somewhat better. While acute nitroing poisoning has been definitely recognized Dr. Herrick stated that anything like chronic nitroing poisoning where the patient for fifteen years chews and swallows the same daily was new to him.

He expressed his thanks for the invitation to address the Society and for the very kindly manner in which he felt that his paper had been received.

Recent Literature.

Manual of Psychiatry. By J. ROGUES DE FURSAC, M.D., formerly Chief of Clinic at the Medical Faculty of Paris. Authorized translation from the French by A. J. ROSANOFF, M.D., Junior Assistant Physician, Long Island State Hospital, Kings Park, N. Y. pp. 344. Edited by JOSEPH COLLINS, M.D., Professor of Diseases of the Mind and Nervous System in the New York Post-Graduate Medical School, etc. First edition. New York: John Wiley & Sons. 1905.

Psychiatry has become such a comprehensive science that the manuals of insanity are more inadequate for purposes of instruction than formerly and less in vogue by reason of their necessary omission, for want of space, of subjects or features that are essential to a sufficient knowledge of the subject. We are, therefore, pleasantly surprised to find this small volume as acceptable as it is. The symptomatology of insanity, its various forms, its jurisprudence and even its treatment are set forth, superficially, to be sure, but so concisely, clearly and accurately as to give the pupil in psychiatry a very good idea of what he wishes to know. For this reason the manual will, without doubt, prove to be of practical value as an elementary work which shall serve as a guide to a more detailed and comprehensive study of the new psychiatry. Not a little of its value is due to faithful translation and judicious editing.

Movable Kidney. A Cause of Insanity, Headache, Neurasthenia, Insomnia, Mental Failure and other Disorders of the Nervous System. A Cause also of Dilatation of the Stomach. By C. W. SUCKLING, M.D. (Lond.), M.R.C.P., Consulting Physician to the Queen's, to the Children's, and to the Orthopedic and Spinal Hospitals, etc., etc. London: H. K. Lewis. 1905.

This publication consists of one hundred and twenty-eight pages. As a bit of book making it is marred by the rather poor quality of its illustrations and the insertion of facsimile letters of patients, and some photographs of a few of them as they appeared before and after operation.

While there are some good views taken of the subject in the course of the work, it is, on the whole, characterized by entire lack of system, by a rather extreme view of the evils resulting from the condition of movable kidney, a very superficial presentation of the literature, and an egotism which taken all together make it a book of as unsatisfactory a character as any that have come into our hands for comment.

As examples of the total lack of coherency in the arrangement of the subjects and parts of subjects, the following may be cited:

"Causes of Movable Kidney" appear in two

widely-separated parts of the book, first under the general heading, "Some Literature on Movable Kidney," and again under the general heading, "Symptoms of Movable Kidney," with neither of which parts of the subject do they appear to have any very definite connection. Again we may cite as a singular selection of sequence of subheadings (both with relation to the general heading "Symptoms," under which they stand and to each other), the following: "Albuminuria," "Dyspepsia," "Irritability of the Bladder," "Appendicitis," "Causation of Movable Kidney," "Treatment by Belts," "Appendicitis" and "Treatment by Belts" as symptoms of movable kidney strike us as having a certain flavor of novelty.

If what the writer presents from it represents his view of the literature of the subject, we must confess that his literary horizon has a rather narrow limit. There is scarcely any mention made of French and but the most scanty notice given to German writers; but very few of the really notable writings are referred to. He lays much stress upon the works of American gynecologists, and practically none upon that of the surgeons of that country, or of others except a few in England. Morris is the most notable exception to this general dearth of the strong writers. One fifth of the whole volume consists of quotation from the writings of Dr. Goelet of New York.

The author attributes a considerable number of cases of insanity, some of epilepsy, headaches, lumbago, insomnia, etc., etc., to the existence of nephroptosis, and adduces examples of patients who having had such conditions were cured after the operation of nephropexy.

One of the grounds upon which he rests his belief with regard to the causal relation of movable kidney to insanity is his finding movable kidney in 50% of fifty female inmates in a certain asylum which he visited in Warwickshire. In view of the statement which we so often hear from a certain number of medical men who have charge of hospital out-patient clinics for women, to the effect that they find any where from 40% to 80% of the patients have well marked movable kidneys, and that the larger part of them have no symptoms which are in any way to be referred to that condition, and certainly are in no respect insane in any instance. The similar finding among a similar per cent of insane women lacks any very startling suggestion of proof of causal connection between this renal condition and the production of insanity.

It is to be regretted that the operative treatment of nephroptosis in cases which are appropriate for its application, which are, we believe, a larger number than some medical men are willing to concede, should be advocated by such an extremist as the author of this volume appears to be in some respects, for such advocacy is likely to confirm the prejudice against that form of treatment and thus, perhaps, deprive some of those for whom it would be highly beneficial from being thereby relieved of their sufferings.

Nervous and Mental Diseases. By ARCHIBALD CHURCH, M.D., and FREDERICK PETERSON, M.D. Fifth edition, thoroughly revised. 8vo, pp 937, with 341 illustrations. Philadelphia and London: W. B. Saunders & Co., 1905.

The appearance of a fifth edition within six years is sufficient proof of the popularity of this treatise. Dr. Church has added many brief interpolations to his share of the work in order to bring it more fully up to date. Dr. Peterson has added Kraepelin's classification to the others cited in his opening chapter, and has written two new chapters on dementia precox and manic depressive insanity, embodying Kraepelin's teachings, which hardly harmonize with the other chapters of the work. We regret that a writer of Dr. Peterson's literary taste should adopt the current barbarism, adopted by so many alienists, of "manic-depressive," a term which is neither English nor German, but a slovenly effort to translate the German "manisch" by some one ignorant of both languages.

Genito-Urinary and Venereal Diseases. By J. WILLIAM WHITE, M.D., John Rhea Barton Professor of Surgery, University of Pennsylvania, and EDWARD MARTIN, M.D., Professor of Clinical Surgery, University of Pennsylvania. Sixth edition. Philadelphia and London: J. B. Lippincott Company, 1905.

The former editions of this excellent work were favorably reviewed in this journal at the time of their publication, and we are glad to extend an equally cordial welcome to the present one.

In the sixth edition, the authors have brought the different subjects of which it treats to the level which is demanded by the advances in the knowledge of them that have taken place in even the short time of two years which has elapsed since the preceding edition appeared.

We are glad to note that the part of the volume which is devoted to the consideration of syphilis no longer occupies the illogical position in the midst of the chapters dealing with surgical diseases of the genito-urinary organs, in which it was placed in the first edition, and that it has been put at the end of it instead.

We do not agree with the view expressed by the publishers with regard to the arrangement of the index of the volume, for which they claim especial excellence, for it seems to us to be one of the most difficult in which to trace a given subject that we have ever seen. Apart from this particular feature, the work as a bit of book making, is admirable, and is very well illustrated. Among its best features are the chapters which deal with the subjects of general symptomatology and examination of the urine.

In a work that is so evenly and generally good, it is needless to specify the value attaching to its special parts. It is a refreshing contrast to many of the numerous publications purporting to deal with the subjects included in this branch of surgery, so many of which are of a cheap order, and we once more bid it welcome and commend it to the profession.

THE BOSTON Medical and Surgical Journal.

THURSDAY, FEBRUARY 22, 1906.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS. \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico. \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

PREVENTIVE MEDICINE AT DARTMOUTH COLLEGE.

THE old adage that an ounce of prevention is worth a pound of cure has always been accepted in a casual way but has rarely been lived up to, even in medicine. In fact the tendency has been to neglect the prevention, however vigorously the cure was used afterwards. The fact that the adage is true, however, has been growing upon the medical profession until at the present day, many measures are in use to prevent disease which a few years ago would have been considered so radical that no one would have had the courage to advocate them. Still, in spite of the great progress along the lines of preventive medicine, there is much that is left undone. While a road here and there may be blocked many others are left open. It is seldom that the work is carried through to a logical conclusion by blocking all the roads. This involves so much which seems useless to the average citizen that in the average community the willing co-operation which is necessary for complete success is not yet attainable. This is especially true of the large cities where the officials appear to the masses as men set over them by some foreign power. In the smaller communities, however, where life is more intimate, this antagonism may be wanting. It is here, therefore, that hygienic reform should be carried out most easily after education has done its work, and nowhere should the cognitions be more favorable than in our colleges where the government is more nearly paternal than in the city, and where people and property are under one control. In fact, there are left few of the colleges today which do not have medical officers to look after

the health of their students. But even their work is along the lines of cure rather than of prevention. Contagious cases are isolated and rooms disinfected, but as a rule little more is done.

In this respect the work at Dartmouth College is unique. How thorough this can be seen in a recent article in the Dartmouth *Bi-Monthly* by Dr. H. N. Kingsford, the medical director. Dr. Kingsford has personal charge of the work and tells of the system adopted there to care for the student health. Nothing is taken for granted where a personal examination is possible. We read, therefore, that a bacteriological examination of the water is made every month and a chemical examination every four months; that the watershed has been cleared of dwellings; that the sources of the milk supply are systematically investigated; changes suggested where necessary and subsequent visits made to see that these suggestions have been carried out. The halls and corridors of the college buildings are not only cleaned but are disinfected regularly. Cultures of the air of all lecture and recitation rooms, of the basements and of the chapel are taken frequently and if more than a certain number of colonies develop the room is disinfected and search made for the cause. Any sputum found upon the floors or walls of the buildings is examined for tubercle bacilli and if any are found their origin is sought for. In this way two cases of unsuspected phthisis were discovered. Basements are whitewashed and opened to the light and air and the drainage kept in good order. It was simple enough to carry out these measures where only the college property was concerned, but as many of the students lived or ate in private houses a different problem had to be solved there in order to complete the work. Tact and patience, however, cleared away all opposition so that now all of these houses are inspected in the same way as the college property.

This system has been in force only two years and, although this may be too short a time from which to draw conclusions, yet Dr. Kingsford's figures are very suggestive. At Dartmouth attendance at chapel and at lectures is compulsory. Any student who wishes to absent himself must obtain a written permit from the medical director who in this way probably sees nearly all of the cases of sickness. In 1903-4, there were 11 cases of bronchitis; in 1904-5, there were 10; cold in the head, 1903-4, 65; 1904-5, 30; influenza dropped from 59 to 21; rheumatism, 11 to 4; tonsillitis, 20 to 9; measles, 31 in 1903-4 to 4 in 1904-5. Such results would seem to

justify the system, whether considered from the medical point of view or from the financial. The first needs no argument. Of the second, it may be said that it ought to be worth while financially to be able to assure prospective students that every means will be taken to protect them from disease.

As already stated, such thorough work is probably unique in college history. At the very large institutions where the students are scattered over a large territory it may not be possible to carry out the investigations with the same completeness as at Dartmouth, yet much more can be done than is attempted at present. In the college proper all necessary measures can, of course, be taken without difficulty. When, however, the college authorities attempt to extend their work to the private houses it will be necessary for them to secure not only the co-operation of the Board of Health, but also of the householders. The experience at Hanover would seem to show that this will not be so difficult as it appears at first sight. There the Board of Health readily gave its consent to the scheme as did most of the householders. Now and then individuals were encountered who objected to making certain repairs which seemed necessary to the medical director. When, however, they were told that the parents of the students using that house would be notified that the place was unhealthful, they withdrew their objections and made the suggested repairs. It is, therefore, probable that equal rights can be obtained at other institutions; at all events, in the private dormitories and in the larger boarding houses. When once supervision of the smallest details of sanitation becomes the rule in the colleges may we not expect it to serve as an example for larger communities and thus spread the idea of prevention? This should be easier nowadays than formerly, because preventive medicine has played so successful a part in Cuba, in the Japanese war and in New Orleans. It is to be hoped that every college may be stimulated by Dartmouth's example, and that in the end public appreciation of the value of preventive methods may secure the same complete and consistent system of safeguarding the public health.

BILLS BEFORE THE MASSACHUSETTS LEGISLATURE.

EACH year sees a certain number of new bills before the legislature, more or less directly related to medical science or practice, and many old bills with slightly altered faces. Some of these

latter appear with regularity year after year. Among the most conspicuous of these is the usual petition of Elizabeth Stuart Phelps Ward and others looking toward legislation to prohibit vivisection. Section I of this familiar bill this year reads as follows: "No person shall perform on any dog or cat any experiment of a nature causing, or likely to cause, pain to, or disease in, such dog or cat for any purpose whatsoever, either with or without anesthetics." This somewhat radical position is not likely to receive the approbation of the legislature in any greater degree than did its predecessors. The bill for the promotion of anatomical science appears in slightly modified form and is somewhat more inclusive than it has hitherto been. The adjustment which must be made between the legitimate claims of anatomical science and those relating to post-mortem examination must be recognized both by those concerned primarily with the teaching of anatomy and also those interested in the study of disease and its consequences. Any bill which prevents absolutely the examination of patients dying of obscure disease should not receive the approbation of legislators or of the medical profession at large.

An attempt is made in the petition of James M. Curley to provide for the care of tuberculous patients at the city's expense in private hospitals. The plan is to hire not more than one hundred beds, paying not more than five dollars each a week for them to be used by needy tuberculous patients of the city. Such a provision has obvious defects, and we have no doubt will not meet with popular approval. Other bills relate to the question of a site for a convalescent sanatorium for tuberculous patients in the towns of Saugus and Melrose. Two bills are offered relative to the protection of the health of school children, the more elaborate of which is presented by Dr. Richard C. Cabot and others. The object of this latter bill is to safeguard children against contagious and infectious disease, to be brought about by the appointment of school physicians and by a careful reporting on the part of teachers of signs of ill health among the pupils. The spirit of this bill is excellent, and if passed certainly should conduce to an amelioration of present conditions. Various bills are presented looking to the control of preparation containing either powerful drugs, narcotic or cocaine, of the oral alcohol. These are all directed toward greater publicity in the sale of such substances, and as such should meet with general approbation.

Bills which have become familiar through repetition are several relative to the sale and use of fire-crackers, premature burial, expectoration in public places and the granting of degrees by the Massachusetts College of Osteopathy. It is apparently difficult to persuade the public that noise is not an essential feature of the celebration of Independence Day. It is, therefore, probable that the day this year will be much as it has been in the past. It is, however, to be hoped that the elements of particular danger associated with certain types of explosives and toys may be eliminated by law at the earliest possible moment. It is unfortunate to bring again to the front the bugbear of premature burial, which, in some few minds, has apparently become a fixed idea. It is not for a moment to be supposed that the elaborate provisions of this bill will be acceptable to the majority of thinking persons. Expectoration in public places should, by some means, be prevented. We were, however, under the impression that the present law if enforced, would cover the matter sufficiently. The complicated questions of the practice of medicine and the registration of physicians are the subjects of bills as heretofore.

A bill to provide for certain public reports by the State Board of Health is undoubtedly a good measure, but chimerical on account of its expense. An attempt to regulate the practice of professional nursing for the sick is likewise open to question. The multiplication of licensing boards must stop somewhere. Already physicians, dentists, veterinarians, pharmacists and undertakers are licensed, and at this session of the legislature it is proposed to create boards for licensing nurses, barbers, clairvoyants, including palmists, fortune tellers and astrologers, and osteopaths. The bill regarding osteopathy deserves a mention of the degree of doctor, which would probably mean the disappearance of the letters D.O. on signs in favor of Dr. A similar bill, introduced by Senator J. H. Walker to compel the use of quarantined by order of board of health. The bill is carefully drawn and is intended to protect the wage earner of a family and to ensure that children may be dealt with in a most judicious manner. One of the most important bills before the legislature is the petition of Dr. Charles H. Johnson to provide legislation to the control of the sale of certain substances, the preparation of which requires that a certain quantity of the substance be given to the patient in the form of a supply has now and keep the same. The object of the bill is to prevent the sale of a

in shops and homes where they are used for all sorts of purposes and then sent back to the farmer who is obliged to clean them. As an example of what may happen, in one case the board's inspector found a complete miscarriage in an eight-quart can. This bill has passed the Senate and certainly should become a law.

In general, the perusal of the bills of this year shows no very radical departure from the yearly legislation. It is unfortunate that certain bills, almost certainly incapable of passage, should be brought forward, year after year, with a renewal of argument which should once and for all be final. The continual re-adjustment of medicine to the complicated affairs of the community is, however, a matter of the greatest importance, and bills carefully framed should receive the attention of the medical profession at the hearings much more than is often the case.

MEDICAL NOTES.

THE GERMAN RÖNTGEN SOCIETY. — It is announced that the second congress of the German Röntgen Society will be held on the 1st and 2d of April, 1906, instead of on the 8th and 9th, as originally announced. The congress will be held in Berlin.

THE NATURE AND CAUSE OF OLD AGE. — Prof. Charles H. Minot of the Harvard Medical School will deliver the tenth lecture in the Harvey Society course at the New York Academy of Medicine on the evening of Saturday, Feb. 24, the subject being "On the Nature and Cause of Old Age."

ONE HUNDREDTH ANNIVERSARY OF THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF MARYLAND. — The Medical Department of the University of Maryland proposes to celebrate its one hundredth anniversary in May, 1907, and is now taking the necessary steps for the organization of such celebration.

BARON KANEHIRO TAKAKI. — Baron Kanehiro Takaki, M.D., F.R.C.S., F.R.S.P., General-Surgeon (reserve) of the Japanese Navy, was in Boston last week as the guest of Dr. John C. Munro and visited the principal hospitals and objects of interest, expressing much approval of what he saw. He also delivered a short address to the students at the Harvard Medical School.

NATIONAL DRUG LEGISLATION. — Representative Webb, of North Carolina, according to the February issue of the *Druggists' Circular*, has

redrafted his bill, the object of which is to compel the names of the ingredients of proprietary medicines to be printed on the labels of such goods used in interstate commerce, and also the amounts of any of the following which may be present: "Opium or any of the preparations of opium, cocaine or salts of cocaine or preparations of cocaine, or morphine or preparations of morphine or salts of morphine, or chloral, or any of the preparations or chloral, or alcohol, or eucaine, or heroine."

Another interstate bill of interest to druggists is that of Senator Hopkins, which provides that when foods or drugs are shipped into a state in original packages or otherwise, they become subject to the laws of that state to the same extent as if made in the state.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Feb. 21, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 68, scarlatina 19, typhoid fever 4, measles 183, tuberculosis 42, smallpox 0.

The death-rate of the reported deaths for the week ending Feb. 21, 1906, was 20.07.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Feb. 17, 1905, was 217, against 223 the corresponding week of last year, showing a decrease of 6 deaths, and making the death-rate for the week 19.02. Of this number 114 were males and 103 were females; 213 were white and 4 colored; 145 were born in the United States, 70 in foreign countries and 2 unknown; 51 were of American parentage, 143 of foreign parentage and 23 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 46 cases and 4 deaths; scarlatina, 31 cases and no deaths; typhoid fever, 8 cases and 2 deaths; measles, 169 cases and 3 deaths; tuberculosis, 32 cases and 26 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 36, whooping cough 0, heart disease 16, bronchitis 8 and marasmus 2. There were 15 deaths from violent causes. The number of children who died under one year was 39; the number under five years, 61. The number of persons who died over sixty years of age was 44. The deaths in public institutions were 70.

A NEW ANTIVIVISECTION BILL. — A bill to prohibit experiments upon certain domestic animals has been introduced in the Massachusetts

Senate and referred to the Committee on Probate and Chancery as usual. A hearing has been set for Tuesday, Feb. 27. The purpose of the bill is stated in Section 1: "No person shall perform on any dog or cat any experiment of a nature causing, or likely to cause, pain to, or disease in, such dog or cat, for any purpose whatsoever, either with or without anesthetics."

MONTHLY BULLETIN OF THE MASSACHUSETTS STATE BOARD OF HEALTH.—Beginning with January, 1906, the official bulletin of the State Board of Health, which has heretofore for twenty-three years been issued as a weekly publication, appears in the form of a small pamphlet to be published monthly. It is proposed in addition to the usual statistical data to present information on sanitary matters of general public interest. The first number gives a report on inspection of food and drugs during December and one on the inspection of dairies. The milk supply of the city of Gloucester is discussed at some length with publication of the names of various milk producers. The first number also contains other matters of interest. It will be sent regularly to residents of Massachusetts who make a written application to the secretary of the Board.

TO ESTABLISH A REFORMATORY AND PROTECT THE PUBLIC HEALTH.—With the above heading, a bill has been presented to the Massachusetts Senate of which the first section provides that a part of the city shall be fenced off for the inmates of houses of prostitution and all other persons of like character, for reformation. The second section provides for a hospital for their treatment by reputable physicians; the third section for a religious church of all denominations for their reformation; the fourth section requires the open wearing of an insignia indicating that reformation is not complete until one year has elapsed from the time of their commencing to reform to its completion; the fifth section demands that the persons shall pay a suitable sum for rental and maintenance, and that the real estate shall pay double the assessed value to the state monthly.

NEW YORK.

GIFT TO HOSPITALS.—The Eastern District Hospital and four other charitable institutions of Brooklyn have received a gift of \$10,000 each from Mr. Peter Wyckoff of that borough.

REQUEST TO STAMFORD HOSPITAL.—By the will of the late John Weed, a wealthy merchant of New York, the sum of \$50,000 is bequeathed

to the Stamford Hospital for Contagious Diseases at Stamford, Conn., the legacy to be designated as the John Weed Memorial Fund.

LIBRARY FOR THE BLIND.—Richard Randall Ferry, originator and founder of the New York Free Circulating Library for the Blind, died on Feb. 16, at the age of seventy-one years. He was a manufacturer, but in 1891 lost his eyesight and retired from business. The library which he established now circulates 10,000 volumes and also provides music and musical instruction for the blind.

IN AID OF STONY WOLD SANITARIUM.—The Stony Wold Sanitarium, the hospital in the Adirondacks maintained by New York women for women and young girls suffering from incipient tuberculosis, has received an offer of \$10,000 from J. Pierpont Morgan, on condition that the corporation raise the balance of \$33,000 required to cover a three years' deficit and meet bonds to the amount of \$10,000 maturing March 1. At a meeting of the managers of the institution, held Jan. 24, it was reported that about three fourths of the \$20,000 asked for had now been subscribed.

DEATH FROM OVER-DOSE OF VERONAL.—The brother of a school-teacher who died recently from an over-dose of veronal has published a statement to the effect that the drug was not procured without a physician's prescription. The young man, it would appear from his account, went to a physician, telling him that he was suffering from insomnia and suggesting that he should give him a prescription for veronal. The doctor, he declares, had never heard of this new hypnotic, but, notwithstanding this, gave him the desired prescription, asking his patient how to spell the name of the drug.

SALARY FOR AN ANALYTICAL CHEMIST.—Commissioner Darlington has secured an annual appropriation of \$1,800 for the salary of an analytical chemist for food stuffs in the Department of Health. When appearing before the Aldermen's Committee on Salaries and Officers for the purpose of securing favorable action in the matter, he urged the great importance of checking the sale of adulterated foods in the city, which he declared to have reached a truly appalling state. "In fact," he said, "there is scarcely an article of food on sale which cannot be purchased in an adulterated form. Not long ago my department got a sample of 'communion wine' which was found to be made up of wood alcohol, hard cedar and an aniline dye. It was a villainously

poisonous concoction, and we are pushing an investigation to see if the same kind of stuff is being sold generally for church purposes." The Health Department has established a chemical laboratory in East 23d Street for the contemplated work, and Dr. Darlington hopes before long to be able to employ three chemists in carrying this out.

BEQUEST OF A BODY FOR THE PURPOSES OF SCIENCE.—John T. Jackson, a sufferer from locomotor ataxia, who recently committed suicide by taking potassium cyanide, left a letter in which he bequeathed his body to science in the following rather extraordinary language: "What I wish you to do, after the usual formalities are through, is to send my body to Bellevue Hospital, where they treated me like a prince for bronchial pneumonia nearly two years ago. Why I want to be sent to Bellevue Hospital, where I have been three times, is for them to cut me, and, most particularly, saw my legs in two below the knees, to see if there is any marrow in the bones; for I have never been free from pain there for seven years, and I particularly demand that they carry out my desire in the cause of humanity and to try to find out if there is a cure for this awful disease."

ESTABLISHMENT OF CITY BEACHES.—A portion of Mayor McClellan's first message to the new Board of Aldermen was devoted to the establishment of city beaches. In treating of the subject he said: "Provision must soon be made by the city toward securing fresh-air homes for children and convalescent patients from the city hospitals, as well as breathing spaces for the whole people. I know of no more ideal location for such fresh-air resorts than one of the beaches on the Long Island shore. Three of these beaches have been suggested as available for these purposes." After referring to Long Beach and Rockaway Beach, both of which possess the necessary advantages, he goes on to say: "I hardly think the Coney Island Beach (which is more accessible than either of the others) would be available on account of its great cost, but it has been suggested that certain charitable organizations, which now own and occupy part of its shore, might consent, in the event of the city's acquiring a beach further eastward, to exchange their present sites for a similar or better location on the city's property. . . . I trust that this matter, in view of its importance to the general health of the city, may be taken up and seriously considered during the coming year."

MONTHLY MORTALITY IN CITY.—The weekly reports of the Health Department show that the mortality in the city during the month of January represented an annual death-rate of 18.72, as against 17.33 in December and 19.44 in January, 1905. Among the diseases in which there was a diminished mortality were the following: The weekly average of deaths from typhoid fever decreased from 11.5 in December to 6.75 in January; the weekly average from diarrheal diseases, from 36.75 to 35; and from cancer, from 58.5 to 56.5. Among the diseases which showed an augmented mortality were the following: The weekly average of deaths from measles increased from 9 to 20.5; from scarlet fever, from 5.5 to 11.5; from diphtheria and croup, from 36.75 to 49.75; from influenza, from 4.5 to 8.75; from epidemic cerebrospinal meningitis, from 15.75 to 17; from acute bronchitis, from 31 to 50; from pneumonia, from 151.5 to 175.5; from bronchopneumonia, from 85.25 to 121.75; from organic heart diseases, from 105.25 to 114.75; and from Bright's disease and nephritis, from 117.5 to 125.5. It is to be noted that the number of deaths from both cerebrospinal meningitis and pneumonia was considerably less than in January of last year, when the weekly average from the one was 27 and from the other 180.25.

--- Miscellany. ---

THE FIFTEENTH INTERNATIONAL MEDICAL CONGRESS.

THE Fifteenth International Medical Congress at Lisbon, April 19–26, bids fair to be one of unusual importance, and, although the number of congressists will be smaller than when it has been held in some of the larger capitals, it will be more select, and papers will be presented by some of the leading lights of the profession in Europe.

The meetings of the congress will be held at the Medical School of Lisbon, which is a very large and spacious building, and will be under the patronage of the King and Queen of Portugal.

The meetings of the sections will take place in the various halls of the building, besides which there will be others devoted to the comfort of the congressists. The largest hall of the building will be a general loafing or club room, in which the congressists can read, write and converse, while two adjoining rooms of large size will be reserved for the ladies of the party. On the terrace of the University there will be a buffet where the physicians can walk about or sit down and have refreshments served at all hours of the day. Everything will be under one roof, and everyone will know where to find everything

connected with the Congress, as well as everything that is needed in a general way. There will be the office of the President, Secretary and Treasurer of the Congress; telephone room; typewriting room; press room; information room, where one can find out all particulars regarding the various routes of travel; halls for showing different apparatus; amphitheaters for giving lantern exhibitions; a postoffice and telegraph office; registration room; money exchange and a room where papers, cigars, cigarettes, etc., will be on sale.

The opening exercises will take place on the first day of the Congress in the hall of the Geographical Society in the Geographical Society building, where a colonial exposition will take place during the meeting of the Congress, under the auspices of the sections on colonial and naval medicine.

There will be a number of addresses or orations delivered each afternoon at the general meeting by distinguished representatives of different countries. Sir Patrick Manson will represent England; Prof. E. von Bergman, Germany; Professor Reclus, Paris; Professor Newman, Austria; Prof. Prince Jean Tarschanoff, Russia; Prof. Azevedo Sedre, Brazil; Dr. Jose Maria Esquerdo, Spain; Dr. P. Aaser, Norway. The names of those from the other countries have not as yet been given out. Dr. Nicolas Senn, of Chicago, has been invited to deliver the oration for the United States.

The amusements for the congressists will be a Portuguese bull fight, three large general fêtes, and receptions and dinners *à la gala*.

There will be two large steamers, one from London and the other from Hamburg, that will take the congressists to Lisbon, and will serve as hotels during the stay there. One of the steamers can accommodate three hundred passengers.

The hotel and other accommodations for the congressists are in the hands of Mr. Manuel Josida Silva, Redaction du Annuaire Commercial de Portugal, Praça dos Restauradores, Palacia Fez, Lisbon to whom all communications concerning board and lodging in Lisbon should be addressed.

All communications regarding the scientific part of the Congress should be addressed to Dr. Ramon Ginteras, Secretary of the American National Committee. All questions regarding transportation to Lisbon and return should be addressed to Dr. Charles Wood Cassett, Editor of the *Medical Herald*, St. Joseph Mo.

A REVIEW OF YELLOW FEVER EPIDEMICS IN MARYLAND

In an address before the general Alumni Association of the University of Maryland delivered Jan. 25 last and published in *Old Maryland*, Dr. James Carroll reviewed the epidemics of yellow fever which have occurred at Baltimore since 1793. It is evident that some

of the profession of that day were keen observers, and our present views in regard to the mode of spread of the disease makes the perplexities which our predecessors experienced in interpreting their observations all the more interesting. Some of them evidently came pretty near the truth of the situation. At the opening of Dr. Carroll's address, we find the following statement:

"Dr. Nathaniel Potter, a former pupil of Dr. Benjamin Rush, and afterward the first professor of Theory and Practice of Medicine in the University, held, in 1793, that yellow fever was not contagious, and he communicated this opinion to Dr. Rush in writing. According to his own statement, he believed that he was the only person in America who held that opinion, and in 1795 he prepared to defend his belief in an inaugural thesis, to be read at the next commencement of the University of Pennsylvania, of which he was a student. He was dissuaded by Dr. Wistar, on the grounds of propriety and expediency. Dr. Potter states that, in 1797, Rush's contention that the disease was contagious was first publicly attacked by Dr. John B. Davidge, one of the founders and the first professor of surgery and obstetrics in this school, whose paper was published in the *Federal Gazette* of Baltimore, on the thirtieth day of November, 1797. Dr. Davidge subsequently enlarged his paper and embodied it in a volume entitled 'Physical Sketches' published in Baltimore in 1814."

ARMY MEDICAL CORPS EXAMINATIONS.

Preliminary examinations for appointment of assistant surgeons in the Army will be held on May 1 and July 31, 1906, at points to be hereafter designated.

Permission to appear for examination can be obtained upon application to the Surgeon General, United States Army, Washington, D. C., from whom full information concerning the examination can be procured. The essential requirements to secure an invitation are that the applicant shall be a citizen of the United States; shall be between twenty-two and thirty years of age; a graduate of a medical school legally authorized to confer the degree of doctor of medicine; shall be of good moral character and habits; and shall have had at least one year's hospital training or its equivalent in practice. The examinations will be held concurrently throughout the country at points where boards can be convened. Due consideration will be given to the localities from which applications are received, in order to lessen the travelling expenses of applicant as much as possible.

In order to perfect all necessary arrangements for the examinations of May 1, applications must be complete and in possession of the Surgeon General on or before April 1. Early applications are, therefore, enjoined upon all interested applicants.

There are at present twenty-five vacancies in the Medical Corps of the Army.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, FEB. 10, 1906.

| CITIES. | Reported deaths in each. | | CITIES. | Reported deaths in each. | |
|------------------------|--------------------------|--------------------------|------------------------|--------------------------|--------------------------|
| | in each. | Deaths under five years. | | in each. | Deaths under five years. |

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING FEBRUARY 14, 1906.

IRWIN, FAIRFAX, surgeon. Detailed as a member of Revenue-Cutter Service Retiring Board, to meet in Philadelphia, Penn., Feb. 15, 1906. Feb. 12, 1906.

OAKLEY, J. H., passed assistant surgeon. Granted leave of absence for one month from March 1, 1906. Feb. 9, 1906.

COMBING, H. S., passed assistant surgeon. Relieved from duty at San Francisco quarantine station and directed to proceed to Yokohama, Japan, for duty in office of American consulate, relieving Passed Assistant Surgeon Dunlop Moore, Feb. 9, 1906.

ROBERTSON, H. McCL., assistant surgeon. Detailed as member of the Revenue-Cutter Service Retiring Board, to meet in Philadelphia, Pa., Feb. 15, 1906. Feb. 12, 1906.

BAILEY, C. A., acting assistant surgeon. Granted thirty days' leave of absence from Feb. 13, 1906. Feb. 13, 1906.

BEHLARD, J. T., acting assistant surgeon. Granted leave of absence for thirty days from Feb. 13, 1906. Feb. 12, 1906.

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING FEBRUARY 17, 1906.

E. H. MARSHALLER, surgeon. Detached from the "Columbia" and ordered home to wait orders.

J. E. PAGE, surgeon. Detached from the "Franklin" and ordered to the "Columbia."

E. P. STONE, surgeon. Detached from the Naval Academy and ordered to the "Rhode Island," Feb. 19.

D. R. KIRK, surgeon. Detached from the "Boston" and ordered home to wait orders.

W. H. BELL, surgeon. Ordered to the "Nevada," Feb. 24.

F. C. COOK, surgeon. Detached from the "Nevada" and ordered to the Naval Academy.

R. R. RICHARDSON, passed assistant surgeon. Detached from the Naval Hospital, Mare Island, Cal., and ordered to the "Boston."

F. E. PORTER, assistant surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the "Rhode Island," Feb. 19.

F. M. BRYAN, passed assistant surgeon. Detached from the Naval Hospital, Yokohama, Japan, and ordered home to wait orders.

SOCIETY NOTICES.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION.—The annual meeting of the American Climatological Association will be held May 12-14 at Atlantic City. The Marlborough-Blenheim will be the headquarters of the association.

HARVARD MEDICAL SOCIETY OF NEW YORK CITY.—At the regular meeting, Saturday evening, Feb. 24, Dr. Frederick C. Shattuck of Boston will read a paper on the present course of instruction in the Harvard Medical School.

J. HILTON WATERMAN, M.D., Secretary.
EDWARD K. DUNHAM, M.D., President.

LECTURE.

THE MIDDLETON GOLDSMITH LECTURE.—This lecture of the New York Pathological Society will be delivered at the New York Academy of Medicine, No. 17 West 43d Street, on Friday evening, Feb. 23, at 8:30 o'clock, by Ludvig Hektoen, M.D., professor of pathology in the University of Chicago and director of the Memorial Institute for Infectious Diseases, Subject: Phagocytosis.

E. K. DUNHAM, M.D., Secretary.

BOSTON BOARD OF HEALTH.

APPOINTMENTS.

MR. WILLIAM H. HAYES of the Charlestown District has been appointed by Mayor Fitzgerald a commissioner of health in place of Mr. Dennis J. Hearn of the Dorchester District, resigned. The appointment is for three years from May 1.

RECENT DEATHS.

WESLEY DAVIS, M.D., M.M.S.S., died in Worcester, Feb. 16, 1906, aged sixty-five years.

DR. PENROCK BROWNING ROGERS, an interne of the Manhattan Eye, Ear and Throat Hospital, New York, died at that institution on Feb. 11. He was the son of Gen. William C. Rogers, U.S.A., now living in Washington.

DR. WILLIAM V. MCKENZIE, president of the Middlesex County Medical Society, died on Feb. 14 at his home in Metuchen, N. J. Dr. McKenzie was also president of the Metuchen Board of Education and a member of the Board of Health.

BOOKS AND PAMPHLETS RECEIVED.

Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition. By Prof. Dr. Carl von Noorden. Authorized American translation. Edited by Boardman Reed, M.D. Translated by Florence Buchanan, D.Sc., and I. Walker Hall, M.D. Part VII. New York: E. B. Treat & Co., 1905.

Text-Book of Anatomy. Edited by D. J. Cunningham, F.R.S., M.D. (Edin. et Dubl.), D.Sc., LL.D. (Glasg. et St. And.), D.C.L. (Oxon.) Second and thoroughly revised edition. Illustrated. New York: William Wood & Co., 1905.

Anatomy, Descriptive and Surgical. By Henry Gray, F.R.S., Edited by T. Pickering Pick, F.R.C.S., and Robert Howden, M.A., M.B., C.M. New American edition, thoroughly revised and reissued with additions by John Chalmers, Da Costa, M.D. Illustrated. Philadelphia and New York: Lea Brothers & Co., 1905.

Indigestion. The Diagnosis and Treatment of the Functional Derangements of the Stomach. With an Appendix on the Preparation of Food by Cooking with Especial Reference to its Use in the Treatment of Affections of the Stomach. By George Herschell, M.D. Lond. Third edition, entirely rewritten. Chicago: W. T. Keener & Co. London: Henry J. Glashier, 1905.

The Treatment of Diseases of the Eye. By Dr. Victor Hanke. Translated by J. Herbert Parsons, B.S., D.Sc., F.R.C.S., and George Coats, M.D., F.R.C.S. Chicago: W. T. Keener & Co. London: Hodder & Stoughton, 1905.

Laboratory Manual of Physiology. By Frederick C. Busch, B.S., M.D. Illustrated. New York: William Wood & Co., 1905.

Rupture of the Gall Bladder. By Benjamin Merrill Ricketts, Ph.B., M.D. Reprint.

Minor and Operative Surgery, including Bandaging. By Henry R. Wharton, M.D. Sixth edition, enlarged and thoroughly revised. Illustrated. Philadelphia and New York: Lea Brothers & Co., 1905.

Genito-Urinary Surgery and Venereal Diseases. By J. William White, M.D., and Edward Martin, M.D. Sixth edition. Illustrated. Philadelphia and London: J. B. Lippincott Co., 1905.

Original Articles.

THE MEDICAL PROFESSION AND THE MEDICAL JOURNALS IN RELATION TO NOSTRUMS.*

BY FRANK BILLINGS, M.D., CHICAGO.

PRIMARILY the medical profession is to blame for the present extensive use of proprietary medicines, the majority of which are nostrums. The law of demand and supply applies here; if we did not prescribe them, they would not be manufactured. "There's millions in it." The medical profession is blind, for we do not see that we are the dupes of men as fertile as Colonel Sellers in schemes and far more practical than he in that they put their plans through to a finish. Commercial cupidity exists in all walks of life. It is small cause for wonder that shrewd men should take advantage of an opportunity that is lucrative and at the same time so easily worked.

The chief causes, as it seems to me, are evident. A large number of the medical profession do not practice medicine rationally. They have no clear conception of disease processes. They do not study and examine their patients. No diagnosis is made at all or only from subjective conditions. Symptoms not conditions are treated. Headache, backache, indigestion, albuminuria, cough, constipation, dysmenorrhea, insomnia, nausea, dyspnea, etc., call for drugs with usually no attempt to get at the underlying cause. I regret to say it, but I believe that many, many physicians practise medicine on that basis. Think for a moment of the vast number of proprietary mixtures, usually nostrums, advertised and distributed in samples to physicians as symptomatic cures.

This sort of practice requires a vast number of these nostrums. He who treats symptoms must necessarily change the medicine from time to time to satisfy and "hold" his patients. He relies upon ready-made, symptom-indicated, dose-directed, usually palatable medicine. He believes what he reads in the "literature" of nostrums sent to him or as it appears in the advertisement found in his medical journal. He forgets that this testimony is inserted for pay. He sees testimonials from professors and practitioners praising the remedy and he believes.

But he is fickle and drops his last specific cure all for a new one which comes to him in sample by mail, or is presented to him by the travelling agent in a confidential and instructive way, and again he believes. He forgets that this agent is either a doctor who has failed as a practitioner, or is an ex-drug clerk whose full worth is commanded by ten or fifteen dollars per week. Usually he is told that the preparation is *ethical*; that its formula is given, usually, however, without indicating the amount of the constituents of the mixture contained in a dose. The process of manufacture is dwelt upon, "after painstaking research" the mixture is so put up that new and heretofore unheard of potency is developed in it.

It is a common experience of druggists to have a rush of prescriptions for a nostrum, which has just been sampled to the physicians in the neighborhood.

For ways that are dark the exploiters of copyright preparations are sufficient and proficient. The nomenclature of these compounds is a wonder. No especial system is followed. A catchy name appears to be the main thing. The name may consist of a euphonious combination of the alleged ingredients; of a morbid symptom or process combined with a drug; of a name indicating the alleged number of ingredients in the mixture, or of any coined word that is striking in print or sound. So we have Sanmetto, Ferroleum, Salochinin, and Peptomangan, Urie-antagon, Antiphlogistine, Zymotocine, Gonosan, Anasarem and Antikanania; Dufonol, Quartonol and Sextonol; and Urtolene, Chloron, Cystogen, etc. Apetizo makes one hungry, and it is said to be an iron food, but Apetol is a strengthener which strengthens, composed of a dozen or more drugs; Rheumagon suggests a possibility that the "rheum" had "gone," but it is said to contain sodium iodide and sodium phosphate and to cure rheumatism and all conditions resulting from uric acid in excess and disturbed metabolism. This is not the only uric acid annihilator for they are numberless. The average proprietor of a trademark preparation looks upon uric acid as one if not the worst enemy of mankind. He offers us uric acid solvents in the form of natural mineral waters (recently these are radio-active as well), artificial waters, salines, plums and effervescent — all things to "touch the liver," and so every one concerned is happy except a majority of the patients.

Often a chemical or drug is used by different proprietary firms in a mixture of other, often, indifferent, substances and presented in powders, tablets, etc., under different copyright names. For instance: Hexymethylenetetramine which is recognized as an excellent antiseptic in diseases of the urinary apparatus is exploited under a dozen or more trade names by as many firms. Cystogen, uniform and auroform are examples. Aetamid is exhibited in mixtures as Bromoseltzer, Antikanan Orangeine, Phenidin, Anemonol, Migraine, etc., by different proprietary houses. Some of these mixtures have even been presented as synthetic chemicals. Well informed physicians believed this until the Council on Pharmacy and Chemistry of the American Medical Association made known the formula after analysis of the mixtures.

It may be well to say that mixtures which contain poisons like opium and other drugs, chloral, cocaine, trepan, etc., and other drugs, etc., should be properly labeled with the name of the drug contained in the mixture. It is common to see cocaine in the eye of a patient suffering from a chronic ocular condition, owing to the continued use of the mixture, or a mixture containing opium, but which is not so labeled, the presence of the drug in the preparation is never advertised as a cure for fever, etc., or simply

* Read at a Library Meeting of the Suffolk District Medical Society (Medical Section), Jan. 3, 1906.

etc., as tonics, as "bracers," etc. I'm very sorry acetanilid was made officinal in the last pharmacopoeia as "pulsif acetanilidi compositus." I think it too dangerous a drug to be used as a medicine, and especially when we have so many harmless substitutes.

But to return to the nomenclature. It is contrary to all scientific standing and progress. It is meaningless. Without a scientific terminology, pharmaceutical preparations cannot be studied or learned. The deception practised by the nomenclature of nostrum is detrimental to all scientific progress and to the morals of the profession and is harmful to humanity. But the nomenclature is linked with a most astounding statement of physiologic action and therapeutic indication in the "literature" of these preparations and in the advertisements in medical journals. Let me quote a few of these statements:

"Hexamine." "It is invaluable in cystitis of all kinds, albuminuria, bacteriuria, gout, gravel, incontinence of urine, pyelitis, irritable bladder from any cause. In typhoid fever it prevents the spread of the infection and destroys the colon bacillus."

Who could ask for anything more definite and universally applicable?

"Sanmetto is not an excitant or stimulant. Its purpose is soothing, healing, restoring. It soothes the irritation, heals the diseased mucous membrane and restores tone to the enfeebled parts. By its use the genito-urinary organs are built up to a state normal with the age of the patient, and thus at the same time any pathological conditions that may be present as a result of their impairment are relieved or cured."

This negative and positive statement of a tonic which soothes and heals and does not excite or stimulate but cures is better than the fabled fountain of youth.

"Antiphlogistine." "It depletes the visceral vessels by flushing the superficial capillaries, bleeds, but saves the blood."

I wonder if any sensible, thinking doctor believes this. If he does I should like to know why.

"Cascia-Metris." "A laxative utero-ovarian tonic, alterative and sedative." "It contains the purely active matter from aletris, cramp bark, wild yam, squaw vine, black haw, blue cohosh, golden seal and cascara sagrada, the inert and objectionable elements being eliminated. Free from alcohol and sugar. Very palatable. A decided advance in modern therapeutics."

Could you ask for any better example of a "shot-gun" dose and that, too, a laxative, a tonic, a sedative and alterative?

"Tongaline." "Antirheumatic, Antineuralgic, Cures rheumatism, sciatica, lumbago, grippe, neuralgia, malaria, headache, gout, because Tongaline contains standard remedial agents of absolute purity, combined with salicylic acid made from the natural oil of wintergreen. Tongaline acts upon the poisonous products of retained excretion or perverted secretion,

and eliminates them promptly and thoroughly, thus insuring in every instance certain results from certain doses in certain time."

Verily, this is too much! At this rate there will be no reason to die. The practice of medicine with Tongaline is too easy.

"Pil Orientalis (Thompson)." "The therapeutic value of ambrosia orientalis (imported solely for ourselves) as a powerful nerve and brain tonic and powerful stimulant of the reproductive organs, in both sexes, cannot be overestimated. It is not an irritant to the organ of generation but a recuperator and supporter."

This ought to answer once and for all time the statement of certain quack advertisers of "Lost manhood, how restored!"

"Sulpho-Lythin." "Is a true hepatic stimulant intestinal antiseptic, antizymotic and toxine eliminator."

This is almost as good as the statement of the old woman of Irish extraction who praised the effect on the bowels of sulphur and molasses, "Sure the molasses iles 'em and the sulphur moves 'em."

"Anasarcin." "Absolute cure of dropsy caused from heart, liver or kidney troubles."

"These are strong words but they are justifiable. From every quarter come enthusiastic reports of clinical results accomplished by prescribing anasarcin not only in dropsies but in exophthalmic goitre. All those natural speculations in the doctor's mind as to the usefulness of this remedy should be immediately dismissed."

The statement of an absolute cure for dropsy of any cause is enough to condemn a preparation.

"Glycozone is daily making converts among physicians for its wonderful work in inflammatory and contagious diseases of the alimentary canal. It is the rational treatment in gastric and intestinal disorders, such as dyspepsia, gastritis, gastric ulcer and all contagious and inflammatory diseases of the stomach and intestines."

Such converts as this stuff makes among physicians are not worth saving.

"Physicians everywhere prescribe Triacol Alpers with unequalled success and perfect satisfaction in bronchitis, coughs, pharyngitis, laryngitis, phthisis, tuberculosis. They prescribe it because it cures."

It is prescribed because it cures *tuberculosis*, bronchitis, laryngitis, etc. The physician who would prescribe it upon the basis of the statement made should have his license taken from him.

"Aletris Cordial Rio is indicated as a prophylactic remedy against post-partum hemorrhage, uterine weakness, great development of the fetus and of the adnexa and in those cases where there is a disposition to hemorrhage."

A prophylactic against uterine weakness. (What is it?) Great development of the fetus! Good Lord! What next?

These are some of the statements made in the

advertisements of a few of the many proprietary medicines. The majority of the quotations are from medical journals. One is not surprised to receive the scarlet literature of the nostrums through the mail nor is one especially shocked to find impossible cures and astounding statements in the medical trade journals, for such journals are published wholly in the interest of proprietary houses.

But one is disturbed to find that the regular and otherwise respectable medical journals publish such rubbish as I have quoted. Such advertisements will be found in the *Medical Record*, *New York Medical Journal*, *The Medical News*, *The Boston Medical and Surgical Journal*, *American Medicine*, *British Medical Journal* and *London Lancet*. Recently the pages of the *Journal of the American Medical Association* have been purged of some of the objectionable advertisements, but still contain some medicines with very objectionable statements as to therapeutic effect.

Now I, and I think most people, believe that the advertising pages of a medical journal are a legitimate part of the publication. Editorial responsibility should extend to every part of it. There can be no question of the harmful effects upon the profession of the flood of nostrums. It is, therefore, injurious to promote in any way the use of them. The editor of a medical journal cannot escape the responsibility of the character of the reading matter, and the influence it may have, which appears in his journal.

The term "ethical" appears in many of the statements of the proprietors of nostrums. The word covers a multitude of sins. The standard dictionary defines ethics as "The science of human duty; the science of right character and conduct." The alleged curative properties of preparations quoted above and of many others advertised in medical journals and in the other "literature" circulated in various ways, do not conform in any way with the definition of the word.

Indeed, the method of advertising these "ethical" preparations in the medical press would with very little alteration fit any "patent" medicine advertised. To illustrate I quote from the lay press:

"What is Castoria? Castoria is a harmless substitute for castor oil, paregoric and soothing syrup. It is pleasant. It contains neither opium, morphine nor other narcotic substance. Its age is its guarantee. It destroys worms and allays feverishness. It cures diarrhea and wind-colic. It relieves teething troubles, cures constipation and flatulency. It assimilates the food, regulates the stomach and bowels, gives healthy and natural sleep. The children's panacea - the mother's friend."

This is like the ethical advertisement in positiveness of statement, both affirmative and negative.

"Tonsiline is the greatest throat remedy on earth. Tonsiline cures sore throat of all kinds more quickly, and is a positive never-failing and speedy cure for sore mouth, hoarseness and quinsy."

As this appears in a newspaper, the profession will say it is a quackish statement made to fool the laity. But as bad and worse statements concerning nostrums appear in medical journals,

"Ask your own doctor: if he tells you to take Ayer's Cherry Pectoral for your severe cough or bronchial trouble, then take it. If he has anything better, then take that, only get well as soon as possible; that's the object. Doctors have prescribed this medicine for sixty years. We have no secrets. We publish the formulas of all our medicines."

Now, can you see any great difference in the alleged curative powers and the therapeutic indications of the preparations quoted from the lay journals and the medical press? In fact, there is none. The language used in the advertisement placed in the medical journal is a little more technical and for that reason is often not as rational as the statement made in the lay press.

The medical press is an educator. Through it, more than by any other means, medical knowledge is widely disseminated. It is a power which, when properly directed, yields untold riches for the benefit of the medical profession. But it has an equal power for evil. If it, as an educator, contains material which is false and misleading, even though this is confined to its advertising pages, it does an infinite harm to the profession and to mankind.

I have not met an editor who defends the practice of advertising nostrums. Confessedly, it is done for money, not for the editor, but for the publisher. The excuse offered is that the editor is engaged to edit the medical articles; the publishers print the journal and supervise the advertising department. But this is not explained to the reader. To the average man all printed statement is fact. He believes the printed word, when he would doubt the oral statement. This is the result of our methods of education of children. They are taught to believe all they read. Many persons never discover the fact that as Burns says:

"Some books are lies frae end to end"

And some great lies were never ken'd,

Ev'n ministers, they hae been ken'd,

In holy rapture,

A rousing whid, at times, to vend,

And na'd't wi' Scripture."

The proprietary medicine evil is due chiefly to the credulity of the medical profession. The cupidity of the proprietors and promoters is the second cause, and, unfortunately, the medical journal lends itself to the exploitation of the nostrum. Few of us, probably, realize the extent to which the use of proprietary medicine has grown in a short period of time. To judge by the prescriptions filled in drug stores of large cities, at least 50% of the profession use proprietary medicines.

The statement is made that in New York City about 70% of the prescriptions filled in large drug stores call for a proprietary preparation. The

¹ James J. Walsh, M.D. *Jour. Am. Med. Assoc.*, Vol. 45, No. 2, p. 1702.

statement is a general one and probably not definite. In Chicago I have secured data from two drug stores. In one large down-town drug store 42% of the prescriptions contained a proprietary medicine. This pharmacy fills the prescriptions of physicians who, in many instances, occupy high places in the profession. The second drug store is in a residence neighborhood where chiefly the prescriptions of the family physicians are filled. This showed about 50% of prescriptions calling for out-and-out proprietary mixtures, or containing in part a proprietary chemical or drug. One prescription was for Castoria and California Fig Syrup, equal parts, with directions to take a teaspoonful every two hours. In Boston, there was secured the data from two of the best known druggists. In one, in which 14,895 prescriptions were filled in a year, 38% were proprietary; in the second, in which 12,000 prescriptions were filled in a year, 48% called for proprietary medicines.

Modern medicine has established the fact that specific medication for disease is very limited. The specific sera, used as antitoxins and bactericides, organotherapy in a very limited field; quinine in malaria, and mercury and the iodides in syphilis, comprise the list. A rational use of drugs, preferably in simple form, to stimulate or to maintain the physiologic function of organs embarrassed by unhygienic habits, by an acute infective process or partially crippled by a morbid anatomic process, is the chief reliance of the physician. Palliation of suffering is an important therapeutic measure. The rational, careful and conscientious physician primarily attempts to make a definite diagnosis. The removal of the cause when possible is an important step, with a rational management of the personal hygiene. The drug treatment may be a very important part of the management and it requires a fine judgment to know when and what as well as when not to give drugs in disease.

The pharmacopeia furnishes a list and description of chemicals and drugs, more than enough to meet the wants of the most ardent believer in drug therapy. A good pharmacist can furnish him with the official water, pill, powder, spirit, solution, elixir, tincture, fluid extract, syrup, etc., of the drugs he prescribes. The pharmacist will give him the complete and definite official mixtures. He will be able to furnish his patient with drugs at their true value. The pharmacist will not be obliged to pay an hundred-fold price for the proprietary preparation which in the end is assessed upon the patient. Acetanilid may be bought for not more than 25 or 30 cents per pound. If prescribed in the copy-right preparations it costs many times the trade price.

Scientific progress, professional integrity and character and economy demand the restriction of the proprietary medicine evil. To restrict it the medical schools should teach the student more fully and adequately botany, pharmacology and therapeutics. The medical graduate must know how to observe and interpret the phenomena of

disease and he must know equally well the materials and how to use them, with which he may combat disease. He should know pharmacology and prescription writing. He should know the therapeutic value and power of drugs and their limitations. With a proper fundamental knowledge of this kind, the daily experience will add valuable information in drug therapy which will not be disturbed by the alluring advertisement of the nostrum exploiter.

To overcome the present evil will require publicity. By this means we may be able to arouse the dormant good sense of our erring brother practitioner and induce him to use simple, tried and official drugs. We must induce the doctor to attend medical meetings and to rub against his fellows. But at these meetings we must not permit the exhibition, under our auspices, of pyramids of proprietary medicines and stacks of more "literature" than is offered at the scientific sessions.

We must discountenance the practice of the "faculty" and the practitioner in writing testimonials of the wonderful effects of these cure-alls.

We must induce our medical journals to stop advertising nostrums. The editors of the great journals of the country are to be numbered among the best members of the profession. They can, if they choose to do so, permit the advertisement only of those proprietary medicines which furnish for publication, in the advertisement, an authentic, definite and complete formula. They should also edit the reading matter of allowable advertisements and prevent the abuse of over-statement and the publications of untruths. Secret mixtures and mixtures with incomplete formulae, or with indefinite statements as to the constituents should be refused space in the reputable medical press. With the publication of accurate formulae the physician would be able to judge of the possible virtues of the mixtures. To most of us mixtures with known formula are objectionable. Disease is never quite the same in different individuals and the morbid phenomena are not often expressed the same from hour to hour and day to day. The treatment must be modified to meet the varying problem of the morbid process. This can be done much more helpfully with simple drugs than with intricate mixtures. Secrecy is essential to the success of the nostrum evil. Publicity will kill it. Publicity will educate the physician and the public and teach them not to use secret mixtures which often contain poisonous chemicals or drugs which are kept secret for the purpose of assigning to them alleged virtues and that an extravagant price may be obtained.

Finally, I desire to express sorrow that the present status of the nostrum evil compels me to say a word of complaint of the medical profession. Many physicians to whom I have talked have expressed themselves as more or less guilty of prescribing proprietary preparations. All agree that it has been done thoughtlessly and that its practice has insidiously grown upon them. Many have said it is unnecessary, is detrimental to

scientific medicine, and that the exposé of the Council on Pharmacy and Chemistry would have a most decided effect in educating the profession not to use nostrums.

READY-MADE REMEDIES.*

BY FRANK G. WHEATLEY, M.D., NORTH ABINGTON,
Professor *Materia Medica and Therapeutics*, Tufts Medical College

To add anything of value to what has already been said on the subject of patent and proprietary medicines before nearly every gathering of medical men in the United States during the last year seems somewhat hopeless, but an earnest conviction that the medical profession is in some degree responsible for the present deplorable condition of affairs, and has a certain duty to perform in the warfare against the evil, together with the very kind and flattering invitation of your president, accounts for my presence here.

At the risk of repeating what may have been said many times, I propose to call your attention to recognized definitions of patent and proprietary medicines, to comment briefly on the harm wrought by them, to consider the extent to which the profession have aided in bringing about the present state of affairs, and, finally, to suggest our duty to the public in the future.

"A proprietary medicine is one, the manufacture or sale of which is restricted through patent of the drug, or combination of drugs, of the label, or of the name, or otherwise, or a medicine concerning which the person making it claims a private formula."

"A patent medicine is a drug which is patented, or the name of which is patented; but usually any drug, the manufacture and sale of which is restricted in any way, whether by patent of substance, name, label, or the like, or by secrecy as to the nature and method of preparation."

A careful consideration of these definitions makes it clear that for medical purposes patented and proprietary medicines are alike. I think it will also be granted that the object in either case is pecuniary gain. I know that it is claimed by the proprietors that the object is to secure to the public reliable preparations, but with the wholesale exposures of fraud in this connection staring them in the face, this claim can hardly be maintained. If it be true that any one working in the interests of scientific medicine has discovered some new remedy of value, or some new method of combining old remedies that is an improvement, what is his duty? As well might the surgeon who had hit upon some new device in operative surgery proceed to protect his device by letters patent and perform his operation behind closed doors for a special fee. To say that anything that has to do with the treatment of the sick should be restricted in this way is to say that the practice of medicine is commercialism pure and simple.

It is a matter of common knowledge that the

consumption of this class of products is enormous. That the public is injured physically, morally and financially by these alleged remedies is, I think, not open to question. If it be true, and I am not disposed to dispute it, that a few of these medicines are intrinsically valuable, they make up a very small percentage of the whole, and are in no single instance indispensable to the successful practice of the healing art. Indeed, in my judgment, the prescribing of these few intrinsically valuable remedies by the profession is, on the whole, a monumental blunder and works an endless amount of harm. Probably no one of us would think of prescribing *Peruna* instead of the official *spiritus frumenti*, if we wanted to tickle our patient's palate with a cocktail, but possibly some might order *Listerine* instead of a simple solution of boric acid, and what is the result? Financially, we have robbed our patient, for it has been demonstrated that as much antiseptic value can be obtained from a solution of any of the common antiseptics for one cent, as \$1.95 worth of *Listerine* carries. But the financial aspect, though serious, is not the worst side of it. When a prominent member of the profession writes a prescription for a protected article, he not only puts the seal of his approval on that particular article, but he, unwittingly, of course, throws the weight of his influence in favor of the whole class of remedies. The public are quick to jump at conclusions, and they will say if *Listerine*, a ready-made medicine, is recognized by the doctor, it is fair to suppose that *Peruna* must also be good. Not logical, you say? Granted; but the public is not skilled in logic, and I know from personal observation that exactly that conclusion is reached by them.

That most of us have at sundry times, and in sundry ways, aided and abetted in the use of these remedies, few of us will, I think, have the hardihood to deny. Do any of us do it for our own profit? "Does the jingle of the guinea help the hurt that honor feels?" I am not willing to believe that this is commonly true. Why, then, do we prescribe ready-made medicines? Probably most of us would say because better results are obtained. In some cases I presume this is true. But why is it true? Simply because the average physician of to-day does not know enough about the science and art of prescription writing. If some second Wendell Phillips should talk to this generation about the lost arts, he might well include prescription writing in the list. This ignorance is one of the results of a movement which date back to Bacon's "Essay on the Self Limitation of Disease," a movement which has led us to the brink of therapeutic nihilism, if indeed it has not carried some of us to the bottom of the pit. The emphasis that has been placed upon the importance of hygienic surroundings, proper diet, etc., has led us to look upon drug treatment as something of very little moment. Not many years ago I heard a prominent member of the profession at public lecture in Boston that a medical man should give very little time to the subject

*Read at a Library Meeting of the Suffolk District Medical Society (Medical Section), Jan. 3, 1908.

that if the student was taught not to give anything till he had read up the subject, or consulted with some one of experience, he would get along all right in most cases. If this theory were applied to every branch of medical science, we could very materially shorten the required course in our medical schools. Our medical students must be impressed with the fact that there are certain definite results that can be obtained by the use of drugs, and that a thorough knowledge of prescription writing is a *sine qua non* to a degree. If the student is taught that definite results can be obtained by scientific medication, and is made familiar with all the agents that are considered official, he will be in no need of these ready-made medicines. Most of us prefer a suit of clothes made especially for us, though some of us may be compelled, for financial reasons, to wear the suit made for the average man of our size. But certainly our patients who call us for professional advice have the right to expect from us a prescription adapted to the individual needs of the case, rather than one ready made that has to recommend it the dictum of a financially interested manufacturer. The point I wish to make is that it is sheer ignorance, and an ignorance fostered by our medical schools, that leads the practitioner to say that the ready-made article is superior to the individual prescription, and it is incumbent upon those who have to do with medical education to graduate those who can beat the ready-made article with one made to order. That this tendency to therapeutic nihilism is not confined to Boston, nor to America, is proven by the fact that not long since at a meeting of the leading physicians of Paris an association was formed for the post-graduate study of drugs, the reason given for this movement being that the average graduate of to-day knows little or nothing of the subject. The newly published pharmacopeia contains the names of all the agents that are needed to successfully compete with the ready-made, protected article, and even if a single or several agents of the ready-made class were equal or superior to any that could be obtained in any other way (a condition that in my opinion does not exist), we would still be doing more harm than good in ordering the ready-made article.

A second excuse for prescribing the ready-made article would, perhaps, be that it was an easier thing to do. This is undoubtedly true, but it would be still easier and in most cases better for the patient, to prescribe nothing. That the leaders in the profession do it would, perhaps, be another excuse. But by so doing they lessen the validity of their claim to leadership, and give proof of lack of education, laziness, or an ape-like imitiveness. That commercialism is back of the whole matter there is no doubt. Take away the money-making feature, and the whole fabric would fall with the classic "dull, sickening thud." The financial side of the question involves not only the manufacturers, but the communities in which their business is carried on, and almost the entire press of the

country. If one doubts the tremendous opposition that any legislation that interferes with the business is sure to encounter, let him attend a hearing before a legislative committee. The fellow-townsmen of Lydia Pinkham, or her descendants, J. C. Ayer & Co., and denizens of other municipalities where the business is carried on, advertising agencies, the drug trade, with some honorable exceptions, join forces with the manufacturers to prevent legislative interference. The question is often asked, What is an ethical proprietary preparation? I know of none. In my judgment, the time has come when, in the interests of the public, we are called upon to ignore the whole list. The last national Pharmacopeia has just been issued, and the Dispensary which accompanies it treats of all the agents we need to use. If we will confine our prescribing to articles recognized by this national authority, we shall confer one of the greatest boons upon the public, and, incidentally, upon ourselves, that the annals of medicine record.

PHOTOPHOBIA: A NASAL REFLEX.

BY EDMUND D. SPEAR, M.D., BOSTON.

² *Ἦν δὲ τοῖς μὲν ὀφθαλμοῖς ἐπικολοῖμα τῆς χιόνος ἐλ τις μέλαν τι ἔχων πρὸ τῶν ὀφθαλμῶν πορεύετο. — Xenophon, *Expeditio Cyri*.*

Nor all the Greek soldiers suffered from snow blindness, and in our day the majority of people can gaze with impunity upon "the blinding snow"; which facts give evidence that the eyes are automatically protected from injury from exposure to bright light.

Omitting cases of refractive error, or including those in which the error has been corrected by suitable lenses, it is plain that it is not the eye alone which produces the symptom-reflex known as photophobia.

Neglecting the modern theories regarding effects upon vision from certain rays at the upper end of the spectrum and considering those of light as we know it, it may be inferred that the normal functions of the percipient apparatus are interfered with in some way by conditions within neighboring structures. That there is a relationship existing between the so-called erectile tissues within the nose and not unlikely, in a direct way, with similar tissues about the ciliary regions of the eye has already been shown by many authors, notably among these Ziem, of Dantzie. His first experiments upon growing animals (1879) showing so clearly a direct influence upon development of the orbit and position of the same with relation to the face that it is now easy to predict the course of an obstructive disease of the nasal chambers throughout the life of the individual.

One of the normal reflexes, that of sneezing, will here suffice for an illustration of my contention that photophobia is a nasal reflex.

It is a common experience to have a bright light induce sneezing. No one can suppose that the eye itself is the real source of the irritation which produces the sneeze. The eye serves

merely to convey the impression to the brain (or spinal cord) which, transmitted by the sensitive filaments of the fifth nerve in the nose and more especially in the regions above the turbinates, is sent inwardly again through connecting ganglia to motor nerves which terminate in the thoracic muscles.

The so-called hay-fever paroxysms form an exaggerated type of physiological reflex. These may include all the normal nasal reflexes, lachrymation, sneezing, coughing, hicough and sometimes vertigo with nausea and retching.

I shall illustrate my contention with but a single case which is typical of all such cases, which vary in degree, but not in kind.

A young man employed as a bell-boy in a hotel and obliged to await the calls in front of a row of electric arc lamps was unable to endure what had become a source of torture to him without constantly shading his eyes with his hands. Examination showed no defects of vision. His nose, however, was obstructed throughout the middle fosse by large hypertrophied turbinates. Direct applications to these swellings produced none of the nasal reflex symptoms. Several weeks of treatment, however, brought about a normal degree of sensitiveness so that an application was promptly followed by lachrymation, sneezing and nasal secretion. It was interesting to note that as improvement in his condition took place a bright light would bring on a paroxysm of sneezing, the onset of which was delayed longer each time until finally the light would not cause reaction.

The inference from such an experience should be, therefore, that when light causes sneezing there must be a degree of hypersensitiveness of the nasal membranes, and that when light causes one to blink or wrinkle one's forehead the nose is at fault rather than the eyes themselves. It was not my intention to adduce photophobia as a cause of wrinkles, because many individuals contract the palpebral fissures in order to "stop down" the light in order to obtain clearness of vision.

New Instrument.

NEW INSTRUMENT. TONSIL SCISSORS.

BY JOHN H. BARNETT, M.D., BOSTON,
Assistant, Nose and Throat Department, Boston Dispensary.

In many operations upon and about the tonsils, particularly in children, the ordinary tonsil knives are often impractical, and are never free from danger. To facilitate necessary operative treatment, and to minimize accidents, these tonsil scissors were designed; and have been used by me for some time to incise the follicles of the tonsils, particularly in cases where the patient refuses tonsilotomy, in hard and fibrous tonsils, and more especially, in cases of acute and chronic lacunar tonsillitis.

The shafts of these scissors are 15.5 cm. in length (which is the length of the Hooper adenoid

forceps), with a curved cutting end of 2 cm. in length which is at a radius of 90° from the shaft. The ends are blunt, and the edges are moderately serrated; and the instrument can be used on either side with equal facility, thus affording an opportunity of completing a single or double operation without removing the scissors from the fauces of the patient. The instrument is a very manageable one, having no tendency to invade the area outside that which it is intended to reach; and this is still further guarded against by the fact that the edges of the scissors are serrated, thus preventing the instrument from slipping. The tendency to hemorrhage is also much less than by the use of any tonsil knives. Multiple slits may be made, either vertically or laterally, and portions of the tonsil may be excised at the time of opening of the crypts if necessary.

In cases of acute lacunar tonsillitis, the tonsils are hyperemic and swollen and the lacunae are distended with masses of thick, yellowish-white, cheesy material. In the chronic form of lacunar tonsillitis, the patient is frequently annoyed by recurrent attacks of acute inflammation, as well as by a constant foul, nauseating odor and taste due to the expulsion of one or more of these lacunar plugs into the fauces or the mouth; when by a thorough incising of the lacunae, the attack is shortened in the acute cases, and future attacks in the chronic cases are prevented. Acute attacks, which usually continue for a week or ten days, have been entirely relieved in twenty-four hours after such incising. The application of medicines to the tonsillar tissue is also greatly facilitated after incision; and the lacunar plugs are prevented from forming and being retained in the tonsillar tissue. In chronic cases, where one or more crypts are distended, or cause pain and frequently renewed inflammation, owing to the narrowing of their mouths, immediate relief is obtained by these incisions.

In many cases, one or more of the orifices of these crypts may open into the supratonsillar fossa, which thus forms a pocket for the collection of these cheesy masses, as well as of particles of food, which soon undergo decomposition, causing a foul odor to the breath and interfering with the appetite and digestion, and undoubtedly is often an underlying cause for a peritonsillar abscess. By incising these crypts and obliterating these pockets with the tonsil scissors, the patient is relieved from further trouble due to this annoying and unwholesome condition.

This instrument was made for me by Coleman & Sharpleff.

Clinical Department.

AMAUROTIC FAMILY IDIOCY: A REPORT OF FOUR CASES.*

BY ALEX. QUACKENBOSCH, A.M., M.D., BOSTON,
*Surgeon Massachusetts Charitable Eye and Ear Infirmary; Instructor
in Ophthalmology, Harvard Medical School.*

THIS rare disease of infancy was first described by Warren Tay at a meeting of the Ophthalmological Society of the United Kingdom in 1881. Since that time quite a number of cases have been seen by various observers, but so far as I have been able to ascertain, but one case has been reported as occurring in this vicinity; a case reported by Dr. Wadsworth at the meeting of the American Ophthalmological Society in 1887, as a "case of congenital zonular grayish-white opacity around the fovea"; four cases, three at the Infants' Hospital, and one at the Massachusetts Charitable Eye and Ear Infirmary, have come under my observation.

CASE I. Infants' Hospital, January, 1897. Male, aged fourteen months, of Jewish parents. Family history, good; two brothers and two sisters living and well, one child died of brain trouble at age of fourteen months. Previous history: Child born apparently normal and continued well for four or five months, then mother noticed that it appeared different from the other children, did not seem to gain in strength, was unable to sit up or hold the head up, the arms and legs were moved about in an aimless manner. At times the child cried stupidly, did not appear to see well. One month before entrance to the hospital the baby began to have convulsions. Physical examination: Well developed and nourished, stupid, unable to sit up, cannot hold head erect, extremities flabby and show marked loss of power. Heart and lungs negative. Ears negative. Knee jerks normal.

Examination of eyes reveal the characteristic grayish-white patch, in the macula region, in the center of which is a sharply defined red spot. Optic atrophy. This child was in the hospital at three different times and the prominent features were twitching of face, lids, corners of mouth, numerous convulsions often starting with a sigh and followed by laughter; the records state that the child "smacks its lips" a great deal.

Progressive loss of flesh and strength, death at the age of twenty-two months. No autopsy.

CASE II. Massachusetts Eye and Ear Infirmary, January, 1902. Service of Dr. Wadsworth. Male, aged fourteen months; first child, of Jewish parents.

This case was seen in the Out-Patient Department, hence no full report can be given. The eyes showed the characteristic change in the macula region, with optic atrophy.

This child died at the age of two years. No autopsy.

CASE III. Infants' Hospital, June, 1905. Female, age nineteen months, born in this country of Jewish parents. Family history, good; first child, no miscarriages, no children in either family that died in infancy of any brain trouble. Previous history: Breast fed for fourteen months; child apparently normal until three months of age, when mother consulted physician, but was told baby was all right. The child has never tried to walk or stand, is unable to sit up without falling over, cannot hold head up, never reaches for things or tries to play; very sensitive

and dislikes to be handled; rolls eyes about, but mother thinks child can see. Three weeks ago child began to have twitching of face and convulsions, since then has not taken food well. Always constipated. Physical examination: Well developed and nourished. Fair color; skin in good condition except on feet and buttocks; feet puffy and purple; circulation poor. No signs of rickets. No rigidity of head or neck. Spine flaccid; no spasm or paralysis of arms or legs. Knee jerks equal and not lively. No Kernig's sign; condition of stupor. Lungs normal except for few fine, moist râles at base. Heart, liver and spleen apparently normal. Lumbar puncture negative. Urine pale; 1,014; sl. acid; no albumin. Examination of eyes: Pupils equal and react to light, but child does not seem to follow light; eyes wander aimlessly. Myopia, myopic crescent about disk; optic atrophy; characteristic changes in macula region of each eye.

This case was under observation for about six weeks and, aside from the convulsions, the things noted were difficulty in feeding (the child had to be fed with a tube) and the hypersensitiveness to noise.

CASE IV.¹ Infants' Hospital, November, 1905. Joseph C., aged eighteen months, born of Jewish parents. First child. Family history negative. Previous history: Breast fed eight and one-half months. Child got along all right to the third or fourth month, then seemed to develop slowly; at eight months of age was not considered bright mentally. Has never sat up or attempted to stand or walk. The parents were unable to tell whether child could see or not. For past three weeks there has been a marked twitching of the face.

Physical examination: Under developed and nourished; very flabby skin; fair color; slight cyanosis of lips. Unable to hold up head. Fontanelle $\frac{3}{4}$ cm. but not tense, rather depressed. Cervical glands enlarged; no sign of rickets; incisor teeth, four upper and two lower. No evident paralysis of face or extremities; legs kept extended, resist attempt at flexing, but after rigidity is overcome, very flaccid. Unable to make out patella reflex. No ankle clonus. Heart, lungs, liver and spleen negative. Urine turbid; acid; no albumin; no sugar; 1,030. Lumbar puncture negative.

Examination of eyes reveals grayish-white patch, with brownish-red center, in the macula region of each eye. Optic atrophy. Pupils large and react. While in the hospital this child had to be fed with a tube.

The cause of this disease is unknown; the parents are generally healthy, without specific or tubercular taint, or history of intermarriage. With few exceptions, the cases reported have been of Jewish parentage. Hirsch has suggested that it may be due to a toxic condition produced by the mother's milk. Clairborne reports a case in which autopsy showed a tubercular tumor of the corpora quadrigemina about the size of a hickory nut, and Kuh reports a case in which there was hydrocephalus.

The disease often affects several members of the same family and it usually terminates fatally at about the end of the second year. Sex has no bearing. Infants are born apparently in good health and develop normally to the third or fifth month, then the muscles become weak and flabby, the baby cannot sit up or hold up head;

*Read at the Meeting of the New England Ophthalmological Society, November, 1905.

¹Case presented at meeting of New England Ophth. Society, Nov. 14, 1905.

the mental development is arrested, the child becomes dull and stupid, and this condition goes on to idiocy. Twitching of the face and extremities, together with convulsions, are common symptoms. There may be difficulty of feeding. The reflexes may be increased or not, in some cases absent. The disturbance in the eye is not congenital, but comes on with the general symptoms, when it is noticed that the child does not see well, or that it rolls the eyes about aimlessly. The first thing observed in the fundus is a haziness in the macula region, this develops into the typical grayish patch with a cherry-red spot in the center. This is followed by optic atrophy. Nystagmus has been observed.

For a number of years after Tay's first case, attention was confined solely to the ophthalmoscopic appearances, and Sachs was the first to state the fact that we had to deal with an extensive disease of the central nervous system. Sachs at first thought that this condition was due to an arrest of development, but he now believes, with other investigators, that the condition is a true degenerative one.

As a result of an autopsy Peterson concludes that the brain shows a defective development; his case showed a confluence of the central with the Sylvian fissure; the pathological conditions are limited to the nerve cells of the cortex and the medulla, which were found deficient in number and development.

Sachs found the convolutions small, a confluence of central with the fissure of Sylvius; thickening of arachnoid and pia mater, hardness of cortex. Degenerative changes were present in the cortex, in the cranial nerve nuclei, and in the anterior and posterior gray matter from the cervical to the lowest lumbar and sacral segments of the cord, the greatest change taking place in the larger ganglion cells. From this Sachs concludes that the disease affects to a great extent the entire gray matter of the brain and spinal cord.

Kingdon found a marked descending degeneration of the upper part of the cord.

Treacher Collins examined two cases of Kingdon's and he reported edema of the retina, but his examination was unsatisfactory, as the retina about the macula region was thrown in folds. Mohr found edema of the outer molecular layer, and a degeneration of the outer segments of the rods and cones of the retina.

Ward Holden examined the eyes of Peterson's case, but the results were unsatisfactory, owing to post-mortem changes. Holden also examined the eyes of Hirsch's case. One eye was hardened in Müller's fluid and one in formol. The one hardened in formol showed the gray patch at the macula region as seen during life. He reports no edema of the retina, but finds a marked degeneration of the ganglion cells of the retina, the cells being enlarged and altered in shape. This change in the ganglion cells explains the fundus picture: the oval gray patch occupies exactly that part of the retina where the enlarged and altered ganglion cells are thickest, and at the

fovea centralis, where the ganglion cells are wanting, the choroid shows through, by contrast, as a cherry-red spot. The optic nerve showed degenerative changes.

Shumway and Buchanan have confirmed Holden's views; they report no edema of the retina, but find marked degenerative changes in the ganglion cells.

Medical Progress.

PROGRESS IN GENITO-URINARY SURGERY.

BY F. H. WATSON, M.D., AND PAUL FROHNIKE, M.D.

DIAGNOSIS OF AZOOSPERMIA.

The author¹ states that spermatozoa continue to be produced by the testicles whether the exits from these organs are occluded or not. He regards this as a really important fact as determining the possibility of operative cure in cases of azoospermia otherwise beyond help. To demonstrate the fact he has punctured the testis with a Pravaz needle in a series of patients who had previously suffered from acute epididymitis.

In 12 cases, punctured seven to twelve years after the acute inflammation, spermatozoa were found in all but 2. In 5 cases at a much later period after the occluding inflammation (twelve to twenty-six years) spermatozoa were found in only one instance.

EXPERIMENTAL POLYURIA.

In this paper, Albarran² after showing his excellent results in 64 cases of nephrectomy for renal tuberculosis, contrasts the unreliability of many of the methods in vogue for studying the renal function with those obtained by his own plan. This he calls "experimental polyuria." It consists in studying the elimination of the two kidneys separately under normal conditions and comparing these results with those obtained from a like study under conditions of forced polyuria produced by excessive water drinking. The specimens from each kidney are obtained by ureter catheterization. Albarran believes his results indicate this as the best method for obtaining knowledge of the real working capacity of each kidney.

REPAIR OF OPERATIVE INJURIES TO THE URETER.

By experiments on dogs the writers³ demonstrate that one ureter injured during an operation may be successfully implanted into the other.

³ *Chirurgica*, Arch. Colombiana, Anales del Ministerio de Instr. Publ., General, Colombia, No. 4, No. 13.

EXCLUSION OF ONE KIDNEY.

This research⁴ from Jaboulay's clinic demonstrates that the exclusion of a kidney from further activity by the ligation of its ureter is possible and is a harmless procedure. Two cases are reported in confirmation of the research work done, one of them being an infected kidney.

RENAL ACTIVITY DURING ANESTHESIA.

In a series of experiments upon animals, the author⁵ showed that with both ether and chloroform, the secretion of urine is increased during the stages of incomplete anesthesia, but that during full anesthesia the secretion is greatly diminished. Both these results are more marked with ether than with chloroform anesthesia.⁶

The work is a study of the clinical effects of ether upon the renal activity of ten patients, by systematic observation of the urine before, during and after ether anesthesia. In every instance there was a very marked decrease in urine secretion by the time complete anesthesia was reached, and this decreased secretion became rapidly more marked as anesthesia was continued. During the first six hours after anesthesia the amount of urine increased, but it never reached the normal, and the kidneys regained their power of secreting water much faster than they could eliminate the nitrogenous constituents of the urine.

ANASTOMOSIS BETWEEN THE TWO TESTICLES.

Gatti⁷ experimented with dogs and found that by making an X-shaped incision through the capsula of the two testicles, the exposed surfaces formed when the four corners of the capsules were lifted up could be easily brought into apposition and held there. He advises the operation for traumatic lesions, but not for tuberculous ones, and says that all manipulations must be very gentle to avoid degenerative processes in the testicular tissues.

THERAPEUTIC USE OF TUBERCULIN.

Pardee⁸ used tuberculin in a series of cases of genito-urinary tuberculosis and studied its effects by periodical cystoscopic examinations of the bladder. He thinks that tuberculin is probably the best means at our disposal to-day for combating tuberculosis of the bladder, and that the best results are obtained in cases where the lesions are very circumscribed in character. One of his cases died, possibly, he thinks, from the use of the tuberculin.

TRANSVERSE NEPHROTOMY.

From experiments on dogs Berman⁹ claims that a longitudinal incision into the kidney leaves extensive infarctions and a considerable

formation of interstitial tissue behind it, while a transverse incision did not cause a disappearance of renal tissue to nearly the same extent.

UNUSUAL CASES.

Westphal's¹⁰ case was one of acute cystitis due to malaria, the parasite being demonstrated in the blood corpuscles contained in the urine sediment, and in the blood vessels of the bladder walls. The case was quickly alleviated by quinine.

This¹¹ is the report of a case of suppuration in both bladder and kidneys due to an actinomycosis which was not demonstrated until after death, when a histological examination of pieces of kidney tissue demonstrated many colonies of actinomycetes.

The case reported¹² is one of aneurism of the right renal artery due to the fall from a horse fourteen years before operation revealed the lesion. During this long interval there were periodical attacks of pain associated on three occasions with blood in the urine but no tumor was discovered until a few days before the operation which revealed through a loin incision a large tumor which was ruptured and 200 cc. of clots were emptied from it. Then the renal artery was found to be the seat of a tubulated aneurism and the vessel was clamped close to the aorta. Patient recovered. Four other cases are reported.

A URINE-PROOF DRESSING FOR SUPRAPUBIC FISTULÆ.

Colt¹³ describes his much needed appliance as one which is applied to the surface of the skin without entering the fistula, which drains without any leakage, which does not inconvenience the patient and which needs only occasional attention.

The apparatus consists of two parts which are described with great detail and which consists of a glass drain held in place by a disk of sheet rubber which in its turn is applied firmly to the skin around the fistula by a rubber solution made by dissolving pure rubber in naphtha. The mode of application is described with great care, and the writer believes the apparatus is absolutely efficient for its intended purpose.

PROCESS-VERBAUX.

Dr. P. Lebreton¹⁴ reports five cases of congenital stricture of the urethra. The ages of the patients were respectively six years, eleven years, thirteen years, sixteen years and nine years.

Certain observations of interest were made in connection with these cases. The chief symptom was enuresis in three of the patients. In the case of two of these three it was of nightly occurrence and had been present from early infancy. In the case of the third there was an irregularly

intermittent occurrence, the interval being sometimes two or three weeks in which there was no nocturnal incontinence of urine, after which the condition would return for variable lengths of time.

The most interesting point to the writer of the report was that of crises of acute complete retention of urine lasting ten or twelve hours or even longer, recurring every three days or so, sometimes yielding to hot baths, sometimes requiring catheterization. This phenomenon was shown by another patient than the three already mentioned.

The fifth patient had diurnal and not the least nocturnal urinary incontinence. The enuresis came in this instance in connection with sudden laughter, or quick bodily movements, fright, etc.

Other but less well marked symptoms were: Diminution in size of stream, feeble expulsion of urine, dribbling after the act of urination, more or less painful urination. There is but one symptom which is distinctive from those of the acquired stricture of the adult, which is the urinary incontinence, and the writer points out that the possibility of its dependence upon congenital stricture should always be remembered.

With regard to the sites of the strictures, they are stated to have been in the perineal urethra in three of the cases, in one at the peno-scrotal angle, and in one somewhat posterior to this point.

The calibers of the constrictions were as follows: In the eldest patient, aged sixteen, only was there a stricture of wide caliber (No. 19). In the four other cases the calibers were No. 9 in two, No. 10 in one and No. 12 in one.

Despite the long continued obstruction to the outflow of the urine in these cases, it is noted that in none of the patients were the kidneys involved in any pathological change, so far as could be determined by the urinary examinations or the condition of the patients.

In one of the patients a residual urine of 100 cc. was found to exist. This patient had a typical overflow bladder.

The treatment employed in all the cases was that of gradual dilatation by bougies, and was markedly successful with all but one of the patients, causing, except in this case, an entire and rapid disappearance of the incontinence of urine and of other symptoms.

The patient having recurring attacks of retention, referred to above, proved to be an obstinate case with respect to cure. In fact, on several occasions attacks of acute retention followed immediately the use of the bougies, and although there were periods of amelioration lasting much longer than before the application of the treatment, the patient still had the attacks of retention more or less often when he was lost sight of, the time during which he had been treated being somewhat more than six months altogether. The stricture in this case replaced comparatively quickly. The author inclines to the belief that some of the strictures which are called congenital are in fact acquired during the first years of infancy.

PROSTATIC AND PERIPROSTATIC ABSCESS.

Alexander¹⁵ treats all forms of prostatic abscess by opening them into the prostatic urethra through a median perineal incision, whether pus be confined within the capsule or has extended outside of it, whether it is posterior to the triangular ligament or has extended into the perineum, or into the ischio-rectal fossa.

He is convinced that the treatment of these abscesses by this means is sound. They have healed under the use of this method more readily and with less danger to the patient than by any other way in his practice.

The technique of the operation is described and it is stated that the perineal wound always heals within three weeks and all the urine is passed through the urethra naturally before the end of the second week.

TREATMENT OF THE RENAL PELVIS BY LAVAGE IN CASES OF LITHEMIA, PYELITIS AND CERTAIN FORMS OF NEPHRITIS.

Johnson¹⁶ is of the opinion that lavage of the kidney is not only justifiable, but is a procedure, the importance of which is such as to demand recognition from the profession at large.

Mild cases of pyelitis may be treated by urotropin or salol and rest; for the severer grades, irrigation with the silver salts, boracic acid solutions through urethral catheter, once or twice weekly, is indicated. So also should cases of pyelonephritis be treated. Ureteritis heals under the use of lavage, employing at first mild soothing washes and later the more stimulating fluids.

Johnson goes still further and asserts that benefit is to be derived (in connection with the usual forms of treatment) from this form of lavage in certain cases of parenchymatous nephritis, and, in some degree, he claims that other forms of chronic nephritis also are improved by the treatment.

RESEARCHES ON THE FUNCTIONAL VALUE OF THE NEW CAPSULE FORMED AFTER DECAPSULATION OF THE KIDNEY.

J. H. Zaaier¹⁷ reports the results of further experiments with reference to this point with rabbits, thus: A new capsule is formed after both decapsulation and scarification of the kidneys of these animals, which insured better circulation for the organs than is the case with the normal kidney. By the end of from four to six weeks, both the arterial and venous anastomosis is more effectual in securing freedom of blood circulation than in the normal organ. There is usually more or less adhesion of the fibrous capsule in the cases of patients upon whom the operation of decapsulation is done. He states that the separation or cutting of such adhesions corresponds to the scarification which he makes in his experiments with the rabbits.

Reports of Societies.

LIBRARY MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

MEDICAL SECTION.

HELD JAN. 3, 1906.

CHAIRMAN, R. C. CABOT, M.D. Secretary, E. A. LOCKE, M.D.

DR. R. C. CABOT: Before introducing the speakers, I should like to define some of the terms which we have to use in discussing the subject of the evening.

(a) *Proprietary*.—What are we to mean by a proprietary remedy? I understand it to be a remedy that some one *owns*.

(b) What are we made to mean by *patented medicines*? We must distinguish them from the so-called *patent medicines*. The composition of any patented medicine can be known by any person by sending to the United States Patent Office with a stamp for reply. The great majority of so-called patent medicines and nostrums are not patented but are protected by a trade name.

(c) The essential point about a *nostrum* is that it is a remedy the ingredients of which are not known. By the *nostrum* evil we mean the secret remedies the ingredients of which we do not know. I suppose there is no one in this audience who knows exactly just what remedies should be called proprietary medicines. There are some remedies which we all know about. There are some which hardly any of us know. There are a great many on the border line.

There are two essentials which we want to know about all medicines: (1) We want to know what are they composed of. (2) We also want to know that the houses which make them are reliable. We have to trust somebody in all cases. But we want to know who it is that we trust. We do not need to know exactly how the remedy is made. Very few of us could give the time to find out. But we do need to know the ingredients and the proportion of the ingredients and that the firm is a reliable firm.

I went to Portland, Ore., last summer and there I learned a great many things. I had always thought of the secret nostrum evil as a matter of certain misguided manufacturing houses or patent medicine concerns. It had not occurred to me that we, the physicians, were responsible for this. This lesson I had to learn from the forceful and timely address of the man whom I have now the pleasure of introducing to you, Dr. Frank Billings, of Chicago.

DR. FRANK BILLINGS, Chicago, read a paper entitled, THE MEDICAL PROFESSION AND THE MEDICAL JOURNALS IN RELATION TO NOSTRUMS.¹

And DR. FRANK G. WHEATLEY read a paper entitled: READY-MADE REMEDIES.²

DISCUSSION.

DR. DAVID W. CHEEVER: It would be idle, it seems to me, in these times, to try to oppose the advancement in chemistry and the skill of manufacturing which is so effectually American, and the force of co-operation by powerful syndicates who can combine all the forces of nature and of labor, of doing almost what they please; and if we endeavor to oppose such it would be, perhaps, questionable whether we were doing the best thing. But, on the other hand, we have to think of two things: first, the duty that we owe to our patients, and second, the duty that we owe to the public. We are called to visit the sick. We are expected in the first place to endeavor to find out what is the matter with

them. They look to us not only for an opinion, but for a remedy. It is for us to say whether that remedy shall be healthy, sound advice with regard to their habits or the condition of their case, or whether it shall be by giving medicine or drugs. If drugs are included in the duty we have to perform to this patient, then it is doubly our duty to know the character and qualities and the purities of those drugs.

When I was young in the profession it was the custom to pay much more attention to pharmacy and materia medica than now, and personally I had what I thought was always a useful privilege. I made up the medicines which I gave my patients so that I became somewhat familiar with drugs. I had not been long in practice before I was told by an older practitioner than I that I was foolish to concern myself with pharmacy. He said, "Let the apothecary attend to that. That is his business. We have nothing to do with the nature or the purity or the strength of drugs. We have only to prescribe and let them carry it out."

Now it has always seemed to me that prescriptions which are made up at the time and made by one reliable apothecary are more likely to be pure and fresh than those which have been made up for some time and have lost their value by being kept. So it seems to me we owe it to our patients in every sense to possess a good knowledge of the effects of drugs, to know enough not to put together incompatible things, to know enough to give drugs by themselves, and to give them in such a soft form that they can be speedily dissolved and not pass through the body whole as is sometimes the case.

A good apothecary who could make his living by following the prescriptions of physicians alone would be the best agent we could employ for the good of our patients. Now I conceive that the great danger in all these secret remedies, and I turn now especially to the duty we owe to the public, consists in the fact that the manufacturers do not say what they contain or that they lie about what they contain, and in the statement that they do not contain certain narcotics when, in fact, they do contain them. I remember going to a case where a child was dying of convulsions and seeing the mantelpiece covered with several bottles containing soothing syrups.

Now there are four or five drugs that are especially dangerous in secret preparations. They are opium, chloral, cocaine, coal-tar products, and last, but not least, alcohol. It is well-known among ourselves how often it happens that although we do our best to avoid it, we sometimes establish and regret the establishment of a morphine habit in our patients. Given first to allay pain its use is then followed up and becomes a habit.

Now, if a patient comes to us and we prescribe certain remedies which we say do not contain morphine and which do contain morphine, a habit may be readily engendered for which we are, in my judgment, directly responsible. In other words, we prescribe an unknown thing and it is certainly as much our fault as that of the manufacturer.

DR. J. C. WHITE: I desire to appear sincere in what I am about to say. I have been practising medicine just fifty years. In all that time I have never prescribed a single remedy outside the lists of the pharmacopoeia of this or other countries.

As has been said here repeatedly to-night, the success, of the manufacture and sale of secret nostrums and proprietary medicines lies in the advertisement in the daily and professional press. Without this information given thus to the laity and to our profession such a thing as the manufacture of these articles would be unknown. The same may be said of the

¹ See p. 231. ² See p. 235.

religious press, so-called, and also against literary journals in the form of weeklies, monthlies and quarterlies. Some of them are decent and clean. We have to handle a great weight of these advertisements every time we read many of these journals. Now it seems to me that we are responsible and seriously at fault in this matter.

I believe that we should withdraw our support from every medical journal in this country, both in the way of subscriptions and contributions, which admits notices of secret nostrums to its advertising columns. I believe that a few medical journals adopting that plan would meet with general support, and would not have to depend upon these advertisements for their pecuniary success.

There are certain other methods to which I think some attention should be given. We should keep agents of proprietary medicines from the house. There should be established in every place a pharmacy which would bind itself to have no dealings with such drugs whatever and to supply only pharmaceutical preparations. It would receive the support of at least 50% of the profession. I believe it would be a practical step in the direction at which we aim.

DR. R. C. CANNON: Dr. White's suggestion seems so important to me that I want to take a moment to repeat it in my own way. If a medical journal were to take the stand that it would exclude nostrum advertisements from its pages, that medical journal would appeal to the medical public and would receive its support. I believe the profession would respond and that those clubs, of which there are a great many in Boston, who now subscribe to journals, would see that it was their duty to support the journal. These advertisements are put in because the profession does not support the journal.

DR. F. C. SHATTUCK: I will simply bring up for one moment the history of the *Index Medicus*. There were no advertisements in that journal, and a sensitive profession might have supported it with zealous enthusiasm. It was of the utmost value to have in every library a copy and it was worth while for the profession to support that journal. In the first year the subscription price was high. Men paid fifty and one hundred dollars for a few years to help it along. After a while the price got down to five dollars. It was allowed to die and it has been revived only by the money that Mr. Carnegie has given. We are thus the recipients of his bounty.

DR. JOHN LOVETT MORSE: I am sure that we all appreciate the importance of this subject and realize our indebtedness to the Council of Pharmacy and Chemistry of the American Medical Association for the work which they are doing. I think we ought also to realize how much we owe to the *Ladies' Home Journal* and *Collier's Weekly* for bringing this subject before the public, as they reach the public in a way which the doctors do not. I wish to present the following resolutions to the Section:

1. Resolved, that the members of the Suffolk District Section of the Massachusetts Medical Society here present heartily approve of the action of the American Medical Association in establishing the Council of Pharmacy and Chemistry for the purpose of investigating and reporting upon non-official drugs, and cordially welcome the results of the work already done by that Council.

2. Resolved, that we give our hearty support to the educational campaign now being carried on by *Collier's Weekly*, by the *Ladies' Home Journal* and by the *Journal of the American Medical Association*, and that we warmly commend the action of these journals in exposing the humiliating subservience of the press,

lay and medical, to the mandates of the Proprietary Association of America, and for showing up the fraudulent use of sham testimonials and the loss of life due to the use of the products exploited by members of the Proprietary Association.

3. Resolved, that copies of these resolutions be sent to the journals mentioned in the foregoing resolutions.

DR. MORRIS PUTNEY: I was led to believe, when you asked me to take part in this discussion, particularly in view of that interesting pamphlet which was sent to each of us (the extract from *Collier's Weekly*), that the discussion would be rather along the lines of the so-called "patent medicines," the quack medicines proper, that are advertised in the daily press, rather than those secret nostrums which are advertised for the most part in the medical journals. What was described in that little pamphlet regarding the control of the press by patent medicine concerns shows a most astonishing state of affairs, one that must be a surprise to most people; but a still more astonishing state of affairs has been brought to light by another magazine, *The Ladies' Home Journal*, in an exposé of the methods by which those patented medicines are exploited. The investigations of Mr. Mark Sullivan, published in this magazine, deserve to be circulated along with those of *Collier's Weekly*.

The facts as brought to light show a very marked difference between the methods of exploitation employed to dispense the secret nostrums, commonly known as quack medicines, and those employed to dispense what more properly may be termed secret pharmaceutical preparations. The difference from a moral point of view is so great in principle that we should hesitate before we class the manufacturers of the two classes of medicine together.

In order to bring out this difference and emphasize the point I would make, I would like to briefly recall the published facts regarding the exploitation of quack medicines. These do not seem to be so well known among the male members, at least, of the profession, as are those connected with the control of the press. Briefly stated, one of the commonest methods in vogue for exploiting quack medicines and one of the worst evils is the treatment by correspondence. The facts which have lately been brought out would be amusing, were it not for the fraud and the swindling of the poor dupes which have resulted.

The method is this: The patent medicine concern invites correspondence, advertising to give advice free. In reply to these advertisements an enormous number of letters is received. For the purpose of replying to these letters and prescribing, a certain number, say, thirty, stock letters are written. These letters are devised so as to cover pretty nearly any group of symptoms of which a person may complain. When the morning's mail brings the letters of inquiry asking advice, each letter is marked with a number and turned over to a typewriter. The number corresponds to one of the stock letters, which the typewriter turns off as if a personal letter, and which ends with directions to take the secret nostrum.

Here are two frauds committed:—one against the state, which requires that every practising physician should be licensed, and yet these concerns practice medicine without a license; and, second, a fraud against the poor dupe who imagines that her case is really being diagnosed and treated. To these may be added the third fraud,—that a perfectly useless, fraudulent medicine is dispensed and money obtained under false pretenses. To me the greatest objection against patent medicine and this system of duping them is that the whole thing is a fraud from beginning

to end. It is a method of cheating and swindling, — a method of getting money under false pretences, and I see no reason why it should not be punished as other methods of swindling are punished.

How far the medicines in themselves do harm, I do not know, but according to a report of the Massachusetts State Board of Health, most of the so-called tonics and bitters contain alcohol, in amounts from 6% to 47%. They include the Sarsaparilla remedies, which contain 13% to 26%. It is said that the use of such medicines often leads to the alcoholic habit. Whether this is so, I do not know; but the statement has been made by Mr. Mark Sullivan, as a result of his investigation into the subject, that a patent medicine is financially valued according as to whether it is a "repeater." By a "repeater" is meant a medicine to which the user becomes habituated and which obliges him to continue its use. The habit being established, he is obliged to repeat his purchase, and hence the medicine is called a "repeater." It is said that a medicine of which a person would buy only one bottle is of little commercial value. A person must acquire such a habit that he cannot leave it off. This would seem to bear out the assertion that these medicines establish the alcoholic and the morphine habit.

Another indirect bad result of secret nostrum is that it has led to the miserable business of letter brokerage and violation of confidence. The letters received by the patent medicine firms acquire a market value, and though pledged as sacred confidences, are sold to letter brokers, who, in turn, sell them to quack doctors and other concerns for about five dollars a thousand. These letters are then sold or rented over and over again. One of these letter brokers claims to have over seven million letters.

The moral of this is as follows: Of course, a letter would not have a second, third and fourth hand value unless the dupes, like lambs in the stock market, return to the temptation over and over again. After trying one medicine they go to another and so on. As one broker said: "To be sure, they have all tried one remedy or more; but that is all right; they will keep on trying new remedies until they die. Buy or rent a few thousand of those letters from me, at a few dollars a thousand, and tackle them with a new proposition, — something new, with a new name, — jolly 'em along a little, and they'll all come up with the money for a new treatment." These letters are classified according to their complaints, and thus each broker can supply to any medicine concern the kind of letters that it may want. Thus, one broker has on his list: 55,000 female complaint letters, 44,000 bust developer letters, 40,000 women's regulator letters, 7,000 paralysis letters, 9,000 narcotic letters, 52,000 consumption letters, 3,000 cancer letters and even 65,000 deaf letters.

One of the worst features of all this secret nostrum business is the utter demoralization of the legislature, the press and, one might add, of public intelligence, that results from the business. The whole thing is an unmitigated fraud from beginning to end, and should be treated as such, just as any other swindling or bunco game is treated.

I have recalled all these facts, though already published, that we may maintain a balanced condition of mind in judging the demerits of another sort of nostrum, — the secret pharmaceutical preparations. A little consideration will show that these belong to a different class which, though it be condemned, must be judged on different grounds. These latter are intended to be, and I believe are, offered not to the necessarily ignorant public at large, the consumer,

but to the members of the medical profession, who are solicited to prescribe them according to their best judgment in suitable cases. The fact that the ingredients are kept secret may make it undesirable and inexpedient, as I sincerely believe it is, that such articles should be prescribed by the physician. The fact that some of them contain drugs, like acetanilid, which may be harmful and dangerous when the adviser is ignorant of what he is prescribing, as well as the fact that the patient is indirectly led to prescribe for himself and the druggist to dispense such drugs, make it undesirable that remedies of which the ingredients are a secret should be dispensed or sold at all; but surely, it is a question of expediency and not of morals. The business of dispensing quack medicines by quack concerns to the public is a question of lying and deception and obtaining money under false pretences, and should be dealt with by the law-making powers and the courts as such; the jail should be the remedy.

The one is a question of protection against a possible danger; the other of fraud. So far as a secret medicine belongs to the one class, its sale should be discouraged or forbidden. So far as it belongs to the other, its sale should be punished. For these reasons I cannot see my way to agree with the reader that all secret nostrums should be classed together and treated alike.

The reader has made much of the extravagant nonsensical claims made by the manufacturers for the curative value of their nostrums. But here again good judgment requires that we distinguish between those claims which are made to the medical profession, — educated physicians, — and the claims made for that other class of proprietary medicines of which I have spoken and which are made to the ignorant public. I cannot believe that any large part of the medical profession is as credulous, as ignorant, so poorly educated and such dupes as some would have us believe. I am sure it is not so in the East. If it be true, it is a terrible arraignment of our medical schools. The average practitioner, while believing the claims to be nonsense, is willing to try any new secret proprietary medicine as he will a new drug, with an incomprehensible chemical formula, supposed thereby to be known.

Nevertheless, it would have a wholesome effect upon the community if the prescribing, dispensing and sale of all secret nostrums could be prohibited. The ingredients of every medicine offered for sale should be made public. The true remedy for the present state of affairs lies, of course, with the legislature, but in the absence of legislation, the question is presented as to what is the most practical and expedient course to pursue. It is, to my mind, a difficult problem. Should the onus be placed entirely upon the medical journals which advertise the objectionable articles? It is to be remembered that if the journals advertise, the medical profession prescribes. This means that public medical opinion to-day is on the side of the manufacturers, and it is unlikely that against public opinion anything serious can be accomplished. Undoubtedly, something can be done by securing the co-operation of the medical journals in a reasonable elimination of the most objectionable advertisements. The best journals would probably be willing to co-operate to this extent, but, above all, the public opinion of the medical profession must be educated into the belief that it is unwise and inexpedient to prescribe secret nostrum remedies which may contain known dangerous drugs, and that their manufacture and sale have a demoralizing influence on both the profession and the public.

On the other hand, we must not forget that the profession owes much to the manufacturer. A large part of the profession, too busy to read medical literature, is kept posted in the recent advances in pharmacology and drug therapeutics by the literature freely distributed by the manufacturer. Is there anyone here who has not been indebted to this kind of literature for early knowledge regarding the therapeutic effect of new and valuable drugs?

Finally, though perhaps least, the manufacture of agreeable preparations, in place of the official tinctures, extracts, etc., of the pharmacopœia, has proved a boon to the patient. He will have them whether you prescribe them or not. *Verbum sapientibus sat.*

On the motion of Dr. George W. Gay, it was

Voted, that the chairman of this meeting appoint a committee of three to confer with the owners and editors of the BOSTON MEDICAL AND SURGICAL JOURNAL in regard to ways and means for eliminating certain nostrums from the JOURNAL'S advertising columns.

The meeting then adjourned.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

STATED MEETING, WEDNESDAY, DEC. 13, 1905, AT 8.30 P.M., THE PRESIDENT, DR. JAMES M. ANDERS, IN THE CHAIR.

ARTERIOSCLEROSIS AS A GENERAL DISEASE.

DR. ALFRED STENDEL called attention to the fact that there is at the present time a much wider conception of the rôle of arteriosclerosis as an independent pathological condition and as the underlying cause of various organic diseases than formerly.

Before the contributions of Gull and Sutton hardening of the vessels was considered merely in the light of a mechanical condition obstructing circulation to some extent and establishing conditions out of which a thrombotic obstruction of the circulation or hemorrhage might arise.

The modern study of arteriosclerosis would divide it into three stages:—(1) A primary stage difficult of recognition in its beginning and confusing to the clinician in his efforts to distinguish the part of the etiological factors from that of the arterial disease in the symptom-complex. (2) A middle period during which the arterial disease is easy to recognize but in which secondary organic changes have a rôle of variable importance. (3) A final stage of failure of circulation, organic failure and terminal infections.

In the first stage the direct evidence of sclerosis of the vessels is inconspicuous while certain general symptoms may be present and may be interpreted as the result of the causes that operate to produce a sclerosis of the vessels or, as in some part, the result of already beginning sclerosis. The difficulty of diagnosis lies in determining the respective parts in the symptom complex.

The speaker, in discussing the question of hypertension as a necessary condition in the early part of arteriosclerosis, insisted that his experience led him to believe that the very earliest change was one of loss of elasticity in the vessels and reduced pressure, and that when continued high pressure is met with this is significant of already established sclerosis. He was inclined, therefore, to question the existence of such a stage of presclerotic arteriosclerosis as had been described by certain writers, notably in England.

Among the symptoms of early arteriosclerosis he spoke of loss of vitality, decreased resistance to external conditions, and a tendency to slight infections, nervous depression, various organic derangements,

moderate circulatory disturbances. Taken as a whole, the symptoms of such cases might justify a separation of groups which could be appropriately designated the nutritional, neurasthenic and nervous groups. In the first the general loss of strength, vitality, etc., are the conspicuous features; in the second the vital depression and lowered nerve tone with beginning circulatory disturbance; in the last, attacks of migraine, profound muscular weakness after effort, evidence of disturbance of cerebral circulation, tendency to neuralgia and the like.

In the second period of the disease, when the thickening of the vessels is quite evident upon physical examination, there are also likely to be met with symptoms of organic disturbance such as albuminuria and other conditions of renal disease, palpitation, irregularity of action and other signs of myocardial disease and a variety of cerebral affections; less frequently pancreatic or hepatic diseases may originate from an arteriosclerosis. It is important in this period of the disease that the physician should realize the widespread character of the underlying pathological condition and not fix his attention too closely upon the organ conspicuously affected.

In the last stage when the vitality and particularly the circulation fails, terminal diseases and many other terminal infections, especially pulmonary and puerperal, are likely to occur. There is rarely any difficulty in recognizing the existence of the arterial disease and the part which it has played in bringing about the reduced state of vitality which acts as the predisposition to the terminal conditions.

The speaker suggested that there is a difference in kind as well as in time of occurrence between presclerotic arteriosclerosis, that is, the form which occurs in younger subjects, and the normal involutional senile type. Clinically, these cases distinguish themselves by their more rapid course and by the greater degree of embarrassment of the organs of the body, and, pathologically, in the speaker's experience, by a tendency to restriction to limited areas of the circulation. The more uniform and widespread the process, the more nearly is the senile type, with its gradually developing hardening, approached. When single vessels are seriously involved rapid obstruction of organic function is more likely to occur and the disease is more distinctly pathological.

THE RELATIONS BETWEEN CARDIOVASCULAR AND RENAL DISEASE AND ARTERIOSCLEROSIS.

DR. WILLIAM H. WELCH, of Baltimore, said there never can be an adequate understanding of arteriosclerosis unless the subject is approached from the anatomical, pathological and clinical standpoint. It is a disease attended with extraordinary perplexity and variability of symptoms and sometimes characterized by entire absence of symptoms.

That chronic Bright's disease may be the result of arteriosclerosis, Dr. Welch thinks there is no doubt, the main question being whether or not there are any peculiar anatomical or clinical characteristics of that variety of Bright's disease that distinguish it from the other types. The most common type of arteriosclerosis is of very little clinical importance in such diseases. It is the form that most frequently occurs in people and though it gives the impression of being an advanced chronic Bright's disease, it is not a disease, and gives very little evidence of disease, except an atrophy of the kidney giving rise to a few symptoms.

The discussion hinges, however, upon the question of systemic sclerosis and general arteriosclerosis. The variety of chronic disease that is characterized by degenerative changes in the arterial system, and

in the glomeruli with excessive changes in the arterioles. The main question is, whether or not the change is primary or secondary, and much importance attaches to the nature of the arterial disease in the kidneys in these cases. Friedman found hypertrophy of the elastic and muscular coats a condition which he regarded as degenerative in this stage in the kidney. This view, Dr. Welch said, had been regarded as correct in histological detail but in error in regard to the hyperplasia of the elastic tissue and, to some extent, of the muscular tissue. Dr. Welch thought that the changes in the vessels of the kidneys as well as the changes in the larger vessels elsewhere might be explained by hypertension. That a clear differentiation between primary Bright's disease and primary arteriosclerosis could be made was questioned. He regarded it as probable that all cases of Bright's disease operate primarily by causing changes in the peripheral arteries. In his judgment a large percentage of the cases of the ordinary chronic contracted kidneys not belonging to the arteriosclerotic kidneys on the one hand, or to the cases in which the arteriosclerosis is secondary to the Bright's disease, are the result of the same sort of cause that produces the arteriosclerosis.

Another way in which arteriosclerosis can produce disease of the kidneys was said to be through disease of the heart. In a case of arteriosclerosis with albuminuria and hypertrophy of the heart with failure of compensation, he does not believe it possible always to determine whether the case is one of true Bright's disease, secondary to arteriosclerosis, or the result of the failure of circulation and a moderate sclerosis.

In the relationship of arteriosclerosis to diseases of the heart, the most important question was considered to be that of the relationship to hypertrophy of the heart. With the knowledge that there may or may not be hypertrophy in cases of arteriosclerosis, and that it is a matter of the greatest difficulty to co-ordinate the changes in the arterial system with the heart lesions, the problem presented is not less difficult than that of the relationship of arteriosclerosis to Bright's disease. The hypertrophy of the heart, he said, must, of course, be a response to a demand for increased work. In arteriosclerosis, increased blood pressure is the exception rather than the rule, and there are cases of excessive arteriosclerosis without any increased blood pressure or high tension, and in those cases there is no evidence that the heart is called upon for extra work.

Why in some cases of arteriosclerosis there should be hypertrophy of the heart and not in others was regarded as a question of special interest. From the Leipzig clinic, he said, had come the statement that if the sclerosis attacked the large abdominal vessels, the vessels supplied by the splanchnic nerve, hypertrophy of the heart was liable to follow; while if the sclerosis affected mainly the arteries of the extremities, hypertrophy of the heart was not produced. Dr. Welch said that there were, however, occasional instances of marked hypertrophy of the heart without implication of the splanchnic vessels and now and then definite sclerosis of the splanchnic vessels without hypertrophy of the heart. He thought the question was wrapped up in the question of the cause of increased arterial tension in arteriosclerosis. A suggestion by one authority was that there is needed an increased arterial tension as in heart disease, which condition is not to be interfered with by the drugs of the clinician, the process being a true compensatory one as the hypertrophy of the heart is in valvular lesions.

The relation of arteriosclerosis to sclerosis of the coronary artery was also considered, and an instance

cited in which the sclerosis was practically limited to the coronary artery resulting in the sudden death of an otherwise perfectly healthy man. Autopsy showed nothing but a little atheromatous patch in one of the coronary arteries which had become the site of a thrombus. Again, the sclerosis may be a part of the general condition and associated with the well-known changes in the myocardium mainly in the form of fibro-myocarditis. He regards the fibroid patches the result of circulatory disturbance following atrophy and disappearance of muscular fibers and their substitution by a new growth of connective tissue. These fibroid patches, however, he does not consider responsible for the grave symptoms associated with coronary sclerosis, but that the disease of the arteries themselves causes the grave symptoms.

THE PATHOLOGY AND DIAGNOSIS OF MYOCARDIAL INFLAMMATIONS AND DEGENERATIONS.

DR. JUDSON DALAND discussed the relationship of myocarditis to myocardial degeneration, and is of the opinion that most of the common and important diseases of the myocardium are *degenerations* and not *inflammations*. Diseases of the heart muscle were subdivided into the inflammations and the degenerations, each of which may be acute or chronic, circumscribed or diffused. Clinically, he subdivided them into acute, chronic, systemic and mechanical, and stated that myocardial diseases may be considered clinically as insufficiency of the heart with or without valve murmur. Brief reference was made to the various forms of myocarditis, and he dwelt particularly upon the importance of chronic fibroid degeneration of the myocardium or cardio-fibrosis. He agrees with Huchard and others that this disease is a degeneration of the myocardium due to faulty nutrition, the result of diminished blood supply to the heart muscle caused by arteriosclerosis, and is opposed to the opinion that it is a chronic interstitial myocarditis.

Fatty degeneration is briefly considered, as well as fatty heart, which he subdivides into (1) simple increase in the epicardial fat, which may envelop the entire heart, or follow the grooves of the blood vessels on the surface of the heart, and (2) as an infiltration, the fat extending between the muscle fibers. He lays stress upon the clinical importance of the recognition of anemia in association with fatty heart and agrees with Romberg in the belief that cardiac insufficiency, in the obese, is caused by relative smallness and weakness of the heart muscle due to the disproportionate demands made upon the circulation by general corpulency.

Brief reference was made to brown atrophy and to amyloid, hyaline and calcareous degeneration of the heart.

The impossibility of diagnosing many cases of myocardial disease was emphasized and illustrated. He also stated that certain of these affections may be diagnosed with a fair degree of probability.

He stated that the symptoms of myocardial disease may be grouped under those of cardiac insufficiency, which symptoms are usually absent until dilatation occurs.

REMARKS ON CARDIOVASCULAR DISEASE, WITH REFERENCE TO TREATMENT.

DR. H. A. HARE said that in most cases of vascular disease the heart and kidneys suffer greatly, and that it may be impossible to determine in which of these portions of the body the primary and greatest change has taken place. He spoke particularly with reference to cases in which the vascular change was the dominant factor and in which there was an immoderate

degree of arterial tension without any renal lesions demonstrable by the ordinary symptoms or by urinary analysis, the heart sometimes presenting secondary signs of hypertrophy or of feebleness from fatigue or degeneration. Cases had been studied in association with Dr. de Schweinitz from the ophthalmological standpoint and with the aid of Dr. Stanton who has used the sphygmomanometer.

Three types of arterial tension were described: Those in which persistently high tension is due to spasm arising from prolonged nervous stress combined with certain abuses as to habits of life, food and drink. (2) Those in which tension is high, because in addition to spasm there is gradually developing or has already developed, fibroid change in the vessels. (3) Cases in which after a prolonged period of high tension there more or less suddenly develops persistent low tension in which the arteries are relaxed and distended so that they resemble veins to some degree in their caliber and compressibility. Cases illustrating these types were cited with the treatment instituted.

The important points brought out in the paper were as follows: As fibrosis in the peripheral vessels increases, the muscles of the larger vessels undergo hypertrophy as does that of the heart and it is quite as possible for vascular compensatory hypertrophy to rupture as for cardiac compensatory hypertrophy to do so. This rupture of vascular hypertrophy often gives the heart rest and permits it to recover from its fatigue and so life is saved. It is possible if the peripheral fibrosis is arrested for the vessels also to regain power and a great improvement to occur. The cardiac stimulants are not needed in these cases so much as rest and the skilful use of alternative and vascular sedatives. In cases of high tension due to fibrosis the nitrates can be of little value, and the iodides with rest and massage are useful.

The concluding portion of the paper dealt with the treatment of valvular and myocardial disease.

DISCUSSION.

Dr. J. C. Wilson opened the discussion. He was particularly impressed with the classification made by Dr. Stengel, especially with reference to the cases in which the familiar clinical symptoms of arteriosclerosis are not yet manifest. While he did not think Dr. Stengel had made it particularly easy for the clinician to recognize these symptoms under all circumstances, he thought the effort to recognize any condition of ill health occurring under circumstances of arterial change should be systematically practised. He thought that failure to recognize the fact that arteriosclerosis was not always a generalized process led to mistaking upon the existence of local manifestations.

He thought that perhaps in no group of cases outside the group of general infection was the nosological division of disease more important than in arteriosclerosis. The disposition to look upon the clinical conditions as the result of diseases of the heart, nervous system, kidneys, etc., when the symptoms were really manifestations of the general condition, he thought should be discouraged. He referred to a type of generalized arteriosclerosis observed in emigrants to this country not unlike senile arteriosclerosis in individuals living under more fortunate circumstances.

Dr. GEORGE L. DE SCHWEINITZ referred to his study of lesions in arteriosclerosis in relation to the use of the ophthalmoscope, and exhibited colored charts showing the eye fundus under these conditions. He considered the ophthalmoscope of aid in diagnosis, particularly in the preliminary stage, in prognosis, and in regard to the value of therapeutics. By the

ophthalmoscope he said were discernible changes in the course, caliber, size and breadth of the vessels and changes in transparency and transparency, so that the ordinary retinal vessel becomes white in color with an appearance as if striped with white, hiding whatever it covers.

When the changes in the course, caliber, size and breadth of the vessels give place to actual sclerotic change the overlying artery presses upon the underlying veins. In contrast to the changes observed in arteriosclerosis there were charts illustrating changes from advanced disease of the kidneys, from syphilitic processes in the eye, and from hemorrhages, and edema of the retina.

Dr. W. B. STANTON spoke with reference to the condition of the blood pressure in arteriosclerosis. In one of the cases mentioned by Dr. Hare the pressure had been the highest of any instance under his observation.

Dr. JOHN H. MUSSER said with reference to the classification of arteriosclerosis that in the early periods of the disease this could be only an etiological one; and to secure relief to the patient the etiological factor must be determined. States of the nervous system giving rise to heightened blood pressure must be considered as etiological factors. In the later periods of the disease classification depended largely upon the organ giving rise to dominating symptoms.

A case was cited which Dr. Musser thought offered great encouragement to all practitioners, — that of a patient with well defined arterial changes, extensive hypertension and secondary myocardial symptoms with eye and general vascular changes. The man was desperately ill, the factor of infection being a frontal sinus. Following operation and drainage there had been a general subsidence of all of the general arterial and myocardial symptoms, and, apparently, of all renal symptoms. At present the man is engaged in his profession. Dr. Musser did not agree with Dr. Welch that the finding of an atheromatous patch, as in the case mentioned by Dr. Welch, indicated the limitation of the sclerosis to the coronary artery, and believed that the process must be general.

Arythmia in association with arteriosclerosis, Dr. Musser said, was being looked upon not as an unfortunate factor, but rather as a conservative one and might occur unassociated with serious myocardial degeneration. He pointed out that if with every third or fourth beat of the heart there was cessation of one, or diminution of the force of one beat, there was given a little rest. He has had cases under his observation for many years showing such arythmia even more pronounced, which had been a relief to the patient rather than the opposite. In certain groups of cases he thought, therefore, that arythmia need not be considered a grave symptom.

Dr. S. S. COHEN said that in arteriosclerosis it was important to determine whether or not the symptoms were those of a degenerative process or of a reactive inflammatory one.

Dr. A. O. J. KELLY spoke upon the importance of recognizing arteriosclerosis in its early stages and thought special effort had been directed to this in late years. He thought this might be facilitated by observation of changes in the heart conditions in patients presenting no symptoms referable to the cardiovascular system. In connection with therapeutics he thought that in consideration of the power of different organs to adapt themselves to different conditions of physiology and of pathology, the therapeutic indications should vary in different cases. He said that if the heart was hypertrophied it need not necessarily be treated. He agreed with Dr. Hare that not always were needed cardiac stimulants, but sometimes a sedative was

THE NATIONAL ASSOCIATION FOR THE STUDY OF EPILEPSY AND THE CARE AND TREATMENT OF EPILEPTICS.

FIFTH ANNUAL MEETING, HELD IN NEW YORK, NOV. 29, 1905. THE PRESIDENT, DR. WILLIAM P. SPRATLING, OF SONYEA, N. Y., IN THE CHAIR.

EPILEPSY, THE STRANGEST DISEASE IN HUMAN HISTORY.

THE Presidential Address by DR. SPRATLING was presented under this title. The speaker stated that more than twenty-three centuries ago Hippocrates wrote an astonishingly accurate clinical description of the "sacred disease," as epilepsy was then frequently called. So much obscurity and mystery, so much that was indefinite, intangible and seemingly unsolvable had surrounded this extraordinary malady for thousands of years, that until recently we had apparently accepted the general decree of its almost complete hopelessness, so far as absolute and permanent cure was concerned, and did but little to offset this unfortunate and ancient conclusion. It was an indisputable sign of scientific progress that the time had forever gone by when we could speak simply of "epilepsy," and particularly when we could say, "This man has epilepsy; give him some bromide." The bromides had the power to palliate the severity of epileptic phenomena in selected cases, and even to arrest the attacks for long periods, but the speaker said he did not believe they possessed in themselves the inherent power to cure. While the intricate biologic problems that lay inherent in the cells of the brain, and that under their own or under immediate or remote associated stimuli were capable of inducing epileptic phenomena were still unsolved, more concise and widespread attention was being given to its etiology, and this was sure to bear fruit in time. That it was a disease of the brain, no one would probably deny. That it might have its origin in some cases in causes remote from the brain could not be controverted. That its causes were multifarious seemed easy of proof.

In discussing the work of the National Association for the Study of Epilepsy, Dr. Spratling said its objects were the following: 1. To promote the general welfare of sufferers from epilepsy. 2. To stimulate the study of the causes and the methods of cure of this disease. 3. To advocate the care of epileptics in institutions where they might receive a common school education, acquire trades and receive the best medical care. 4. To assist the various states in America in making proper provision for epileptics.

REPORTS ON PROGRESS IN THE PUBLIC CARE OF EPILEPTICS.

DR. H. M. WEEKS, the superintendent of the New Jersey State Village for Epileptics, located at Skillman, N. J., said that this village was established by an act of the legislature in 1898, and was formally opened for the reception of patients on Nov. 1 of that year. The village contained about 800 acres of land, nearly all of which was under cultivation. There were at the present time accommodations in the village for 300 patients.

DR. M. L. PERRY, the Superintendent of the Hospital for Epileptics at Parsons, Kan., which was opened for the reception of patients in October, 1903, said that the institution now had a population of 340, and a total capacity of 400. The number of patients was steadily increasing, and it would soon

become necessary to refuse applications for admission. There was little doubt, however, that the next legislature would provide for the construction of several additional buildings, and such other improvements as circumstances might demand. The first aim of the institution was to relieve the State hospitals for the insane of their epileptics, and the first patients that were received were transferred from those hospitals. Subsequent transfers had been made until at the present time the separation of those two classes was complete, and there was not an epileptic remaining in those hospitals. Experience had demonstrated the wisdom of that course, and it had proven beneficial alike to the insane and the epileptic. It had been the policy of the institution from the beginning to allow the patients as much individual freedom as possible, consistent with necessary discipline. All of the patients who were not confined to bed or who were not physical wrecks were required to do some work, and they had found this to be one of the most important and efficient adjuvants to treatment. The results obtained by treatment had varied greatly, but, on the whole, had been satisfactory. In some of the patients there had been no improvement whatever, but in a great many others there had been a marked diminution in the number of seizures, with decided improvement in their mental state and general physical health. There were several now under treatment who were considered to be on the road to recovery, and three had been discharged as cured. Of those three, all of whom were well marked cases of epilepsy, two had returned to their homes and work, and had resumed their places in society; the third had been lost sight of. These results might appear to some as trivial and unsatisfactory, but it should be borne in mind that thus far they had been dealing almost exclusively with cases of chronic epilepsy of long standing.

The President, DR. SPRATLING, said that at the Craig Colony for Epileptics at Sonyea, N. Y., they now had under observation and treatment 1,050 patients and 900 applications were on file from epileptics who could not be received for lack of room. The plant represented an investment of about \$900,000 and included 71 buildings, scattered over 2,000 acres. Additional buildings for the accommodation of 200 more patients had recently been contracted for.

DR. J. CLIFFORD SCOTT, the superintendent of the Pennsylvania Epileptic Hospital and Colony Farm at Oakbourne, Pa., said that this colony was supported largely by private contributions and that over 75% of the patients were on the free list. The colony was located on a farm of 110 acres, and had admitted, up to the present time, 161 patients, of whom 9 had died, 2 had been discharged cured, 67 improved and 32 unimproved. Fifty-one patients still remained in the institution. An effort was made to furnish employment that was adapted to the ability and natural tendency of the individual. Outdoor work was, of course, most beneficial, and the men were kept employed, excepting in inclement weather, on the farm, lawn, truck garden and about the buildings. Sufficient vegetables were raised in the garden to keep the table supplied most of the year. The women did most of the household and laundry work, besides having sewing and embroidery classes. Frequent entertainments were given, consisting of musical recitals, dramatic sketches, etc. The results of the colony treatment were most encouraging. The patients became more cheerful and more healthful physically, and without exception the number of their seizures were lessened.

HISTORY OF A CASE OF EPILEPSY OF FIFTY-TWO YEARS' DURATION, WITH 28,000 CONVULSIONS.

DR. MATTHEW WOODS, of Philadelphia: When this patient, a man about fifty-seven years old, first came under Dr. Woods' observation, the history obtained from him and from his mother, who had been his constant nurse, was that he had suffered from severe and frequent epileptic attacks for fifty-two years. The patient himself had kept a carefully tabulated record for many years of his *grand mal* seizures and he had estimated that during his life he had had over 28,000 severe attacks. During the first fifteen years of his infirmity he had consulted many physicians, and had tried numerous remedies without apparent benefit, so that all treatment had long ago been abandoned. Dr. Woods said it was the first chronic case he had ever seen where the patient did not come to him saturated with the bromides. The patient frequently had three or more attacks daily, and scarcely a day passed that he did not have at least one. The treatment advised by Dr. Woods was as follows: An almost exclusively vegetable diet was ordered, only a little meat being allowed, and that in the middle of the day. The patient's supper was to consist of tea or coffee, with bread and butter, and he was told to avoid eating pork, veal, cabbage, cooked tomatoes, pastry and other foods difficult of digestion or apt to excite fermentation. A pill containing 1 10 of a grain of capsicum, 1-30 of a grain of strychnine and 1/2 of a grain of the hydrocyanate of iron was ordered before each meal and at bedtime. Also a dram and a half of the bromide of potassium, divided into four doses, and each dose given with the utmost regularity at 8 and 12 o'clock in the forenoon and at 4 and 8 o'clock p.m. The bromide was ordered to be highly diluted with water, increasing the quantity of water with each dose by 1 oz. each week, until each dose was taken in 12 oz. of water. When the attacks were nocturnal, the last two daily doses should be united and taken at 9 p.m., in a pint of water. After two weeks of the above treatment, during which period the patient had two convulsions, he consented to an operation, under ether, for the relief of a phimosis of long standing. The prepuce was removed, together with three calculi and nearly an ounce of thickened, gelatinous, sub-preputial secretions. This added very much to his comfort and satisfaction, and made a profound impression upon him. Subsequent to the beginning of his treatment, this patient had six convulsions in all; four of these occurred while he temporarily stopped his medicine, and the other two while he was taking medicine, but prior to the operation. His death occurred three years and nine days after his last convulsion, at the age of sixty, and was due to valvular insufficiency.

CAN A COLONY BE MADE FOR THE CARE AND TREATMENT OF EPILEPTICS BE MADE SELF-SUSTAINING? IF SO, HOW?

DR. THOMAS C. FITZSIMMONS, of Wilkes-Barre, Pa., read a paper with this title. He stated that of the obstacles in the way of accomplishing substantial material aid for the epileptic, the most serious was the securing of sufficient money to properly house and care for all classes who suffered from this distressing malady. The question naturally arose, Could a colony of epileptics be made self-sustaining? In the speaker's opinion, it would require from seven to eight years to sufficiently develop a colony institution to place it on a self-sustaining basis. However, with a sufficient acreage, say an average of two acres of arable land to each colonist, and the wise and judicious selection of a soil which should be adapted to the

raising of crops most productive and profitable in that locality, he thought such a colony would become self-sustaining.

STATISTICS OF EPILEPTICS IN HAMPTON COUNTY, MASS.

DR. EVERETT FLOOD, of Palmer, Mass., presented this paper. He stated that in general it seemed to be true that the more familiar we became with a community, the more epileptic cases we found. The population of Hampton County was 175,003. The number of epileptic persons reported in the whole county was 224, a ratio of one to 783; adding 56 as the number of cases that were probably overlooked, it would give a total of 280, or a ratio of one to 550. These statistics were collected in 1900, and revised one year later.

DR. SPRATLING said he could corroborate the statement made by Dr. Flood that statistics of the number of cases of epilepsy were misleading, and that many cases remained concealed. The more that was done for the epileptic, the more that he felt was being done for him, the greater the number of cases that would come to light.

DR. EDWIN A. DOWNS, of Hartford, Conn., said that the ratio of epileptics to the general population given by Dr. Flood corresponded very closely to the figures he had obtained in Connecticut. The difficulty of securing accurate statistics on this point was increased by the fact that many so-called cases of masked epilepsy went unrecognized.

ANNOUNCEMENT OF A \$300 PRIZE FOR THE BEST ESSAY ON THE ETIOLOGY OF EPILEPSY.

The President, DR. SPRATLING, announced that through the generosity of a person who was warmly interested in the work of the National Association for the Study of Epilepsy and the Care and Treatment of Epileptics, the Association was authorized to offer a prize of \$300 for the best essay on the etiology of epilepsy. The conditions of the award were as follows: All essays submitted must be in English, written in a clear, legible hand or on the typewriter, on one side of the paper only, and must not contain more than 15,000 words. They must be in the possession of Dr. W. P. Spratling, at Sonoma, N. Y., not later than Sept. 1, 1906. The name of the person submitting the essay must not appear on the same, but be put in a sealed envelope on which a motto is written, and which should also appear at the top of the first page of the essay.

All essays received will be placed in the hands of three physicians to determine their merit. Two of these physicians will be members of this Association, the third a member of the American Neurological Association.

Announcement of the award will be made at the November, 1906, meeting of the Association, and the successful essay becomes the property of the Association.

The Association will not feel bound to award the prize should no essay submitted be deemed of sufficient value to merit it. Original research work into the etiology of epilepsy will be the leading factor in having the award.

Further information about the matter may be obtained from Dr. W. P. Spratling, at the Craig Colony for Epileptics, Sonoma, Livingston County, N. Y.

THE USE OF A BROMIDE FERRALUMINATE WATER IN THE TREATMENT OF EPILEPSY.

DR. G. KIRBY CANTLER, of Sonoma, N. Y., presented this paper. He said that while the use of the bromides in the treatment of epilepsy had long been recognized

as a valuable adjunct to our materia medica, the many abuses of the drug were well known, as well as their harmful effects. Among these he mentioned chronic bromism, characterized by a loss of appetite, a nauseous, fetid breath, chronic gastritis, constipation, muscular weakness, frontal headache, a sense of mental weakness, failure of memory, congestion of the uvula and fauces, inactivity of the excretory organs and hallucinations. Also various skin eruptions. In order to remove or at least minimize the injurious effects of the drug, Dr. Collier devised the method of administering the bromides with a saline purgative, in order to promote the elimination of the bromine, and to disguise the taste of the two, so that the dosage could be more easily regulated. The method devised was as follows: A concentrated solution of the bromides, the sodium, potassium, calcium and ammonium salts, was made with the addition of magnesium sulphate. Epsom salts was selected on account of its prompt action without giving rise to any nausea or griping, and its diuretic property. The bromides were used in the strength of, sodium bromide, 6 parts; potassium bromide, 3 parts; calcium bromide, 2 parts; ammonium bromide, 1 part; and magnesium sulphate, 8 parts. The bromides and magnesium sulphate in the above proportions were added to a quantity of water sufficient to yield 128 volumes, which gave a concentrated solution. The object in view was to have this so-called bromide water take the place of the ordinary drinking water at meals, 2 oz. of the concentrated solution being added to one quart of water, preferably iced, and the patient given one glass, equal, approximately, to one-half pint at each meal, or oftener, if necessary. It was thought desirable to make this a ferrated water, and to that end one fluid ounce of the tincture ferri-citro-chloroform was added to the 128 parts of the concentrated solution. The use of the bromides in this form was begun in June, 1905, being given to patients who had previously been taking large amounts of the drug, and the method had resulted in a distinct lessening of the number of seizures, and a marked improvement in the general condition of the patients.

DR. JAMES W. WHEERRY, of Danville, N. Y., said that while all recognized the value of the bromides in epilepsy, the harm that frequently followed their use could not be lost sight of. If the combination proposed by Dr. Collier would retain the good qualities of the bromides, and eliminate their injurious ones, it would prove a boon not only to the physician, but to the patient.

DR. SPRATLING said that during his fifteen years' experience with 2,500 cases of epilepsy, he had never yet given the bromides with the expectation that they would ever cure the disease. He took the stand that they had a place in the treatment of epilepsy, but it was wholly secondary to any good they could do in the way of a cure. He had yet to see a genuine case of epilepsy cured by the bromides alone; on the other hand, he had seen an enormous amount of harm come from their use.

DR. M. L. PERRY, of Parsons, Kan., said that perhaps a partial explanation of the good results obtained by Dr. Collier with his bromide-ferrated-aperient water could be traced to the eliminative properties possessed by the combination, and the consequent improvement in the patient's general health. The great difficulty was to get the sedative effect of the bromide without its injurious effects upon the patient's general health and mentality.

DR. MAX MAILHOUSE, of New Haven, Conn., raised the query as to how much of the benefit that followed the use of the combination bromide mixture was due

to the treatment itself, and how much to the other factors that formed a part of the colony treatment. He was inclined to agree with Dr. Perry that the favorable results were, to a certain extent, at least, attributable to the eliminative effects of taking such large quantities of fluid, perhaps by helping to eliminate toxins that were absorbed from the digestive tract.

DR. EVERETT FLOOD, of Palmer, Mass., said that when the sedative effect of the bromide was first discovered, and there was great need for a drug of that character, it was very likely that excessive doses were administered. The time had now come when we should be very careful about the dose and the method of administration, and we knew that a small dose would often answer all the purposes of a large one. He was firmly of the opinion that the drug should be given in smaller doses and at longer intervals. He believed that the bromides still had a place in the treatment of epilepsy, and that we should oppose their misuse rather than their use.

DR. COLLIER, in closing, said the dose of the bromide salts in the mixture was about 11 gr. to the half pint of water; the patient received 11 gr. of the bromides daily, whereas the other patients were receiving from 30 to 100 gr. daily in the ordinary form. The demand for salines and cathartics was also very much lessened while they were taking this mixture.

TRAUMATIC PSYCHIC EPILEPSY.

DR. PEARCE BAILEY, of New York City, read this paper. He stated that focal, or Jacksonian epilepsy, resulting from injuries to the motor cortex, was a clinical condition, thoroughly established, of unmistakable identity, and in which the relationship of cause and effect was incontestable. Traumatic general epilepsy, though its individuality was less well assured, was, nevertheless, recognized by most competent authorities as a legitimate and direct outcome of trauma to the head. Traumatic Jacksonian epilepsy was rarely accompanied by any purely psychic manifestations. General epilepsy from trauma, on the other hand, was not infrequently associated with psychic phenomena. When associated with recurring convulsive seizures there was no difficulty in recognizing the purely mental manifestations as part and parcel with the epilepsy. When, however, all convulsive phenomena were absent, the diagnosis of epilepsy became a much more uncertain matter; and, indeed, it was questionable whether the diagnosis of epilepsy from psychic symptoms alone was justifiable. Neither the periodicity, the amnesias, the automatisms, the periods of depression, nor the myoclonia were in themselves characteristic of epilepsy and of nothing else. This became particularly apparent when observing the occasional mental effects of head injuries. After the initial unconsciousness had passed off, some patients continued to present mental symptoms. They were of a delirious, confusional and especially impulsive character. They might be continuous, or, more frequently, periodic, with normal intervals. The impulsiveness of these patients closely resembled that in the epileptic psychoses. The patient at one moment might talk rationally and coherently; at the next be irrational, irresponsible and violent.

Dr. Bailey then reported in detail a case of traumatic psychic epilepsy, and said the only point he wished to raise was to call attention to the resemblance between psychoses resulting from brain injuries and epileptic states, and to express his own opinion that a differential diagnosis between the two conditions, if they were individual, was often impossible.

DR. M. ALLEN STARR, of New York City, said that several years ago he saw a boy of sixteen, who four years prior to that age had sustained a severe fall on the head. It was not supposed, however, that the skull had been fractured. Subsequent to the fall he developed attacks of a psychic character, which occurred at intervals of from one to two months up to the time he was operated on. The attacks occurred suddenly, when, without any apparent provocation, the boy would fall into an extreme rage, and would attack any one near him. During such attacks he had injured several members of his family, and he had been unable to keep any position. The attacks would last from thirty minutes to an hour, and when they had passed off the patient apparently had no recollection of them whatever. He was brought to the Presbyterian Hospital, where Dr. A. J. McCosh found a scar in the parietal region over the superior parietal convolution. As pressure there was painful, and as the boy complained of a good deal of spontaneous pain in that locality, it was decided to trephine at that point. Upon opening the skull, there were evidences that there had been a slight linear fracture with great thickening of the underlying dura, and underneath this there was found an extraordinary collection of veins, about an inch and a half in diameter. It was a typical angioma, made up of a number of little blue veins which resembled a cluster of small worms. By carefully tying off all the branches leading into this mass, it was isolated and then removed. This resulted in very slight injury to the parietal cortex in that region, but in spite of the fact it was sufficient to produce a temporary ataxia of the corresponding hand, without any accompanying paralysis. The boy otherwise made a perfect recovery, and from that time on was relieved of these periodical attacks of rage.

ROBGRAPH OF VARIOUS TYPES OF EPILEPTIC SEIZURES.

DR. WILLIAM P. SPRATLING, of Sonoma, N. Y., and WALTER G. CHASE, of Boston, Mass. (See BOSTON MEDICAL AND SURGICAL JOURNAL, p. 571, 1905.) The following officers were elected for the ensuing year: President, Dr. Max Mailhouse, of New Haven, Conn.; First Vice-President, Dr. Everett Flood, of Palmer, Mass.; Second Vice-President Dr. William F. Drewry, of Petersburg, Va.; Secretary and Treasurer, Dr. James W. Wherry, of Danville, N. Y.

Recent Literature.

The National Standard Dispensary.—Containing the Natural History, Chemistry, Pharmacology, Actions and Uses of Medicine including those recognized in the Pharmacopœias of the United States, Great Britain, and Germany, with numerous references to other Pharmacopœias. In accordance with the eighth decennial revision of the United States Pharmacopœia, 1905. By HENRIK ARVID HALL, B.Sc., M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. CHARLES CASPARI, JR., Ph.D., Ph.D., Professor of Theoretical and Applied Pharmacy in the Maryland College of Pharmacy, Baltimore. HENRY H. RISBY, M.D., Professor of Botany and Materia Medica in the College of Pharmacy of the City of New York. JOSEPH F. GRIFFIN, Ph.D., Chemist, New York State Department of Agriculture.

EDWARD KREMLER, Ph.D., Professor of Chemistry, University of Wisconsin; and DANIEL BASE, Ph.D., Professor of Inorganic and Analytical Chemistry, University of Maryland. Illustrated Philadelphia and New York: Lea Brothers & Co. 1905.

This new edition *Standard Dispensary* succeeds the *National Dispensary* of Stillé and Maisch. In addition to a consideration of the subjects contained in the new United States Pharmacopœia, it covers also the ground of unofficial drugs and preparations now generally in use. This has necessitated a consideration of many new subjects. Minor drugs, as well as those of recognized importance, are discussed in such a manner as to leave the reader with a definite knowledge of their relative value. In connection with the action and uses of drugs, an attempt has been made to epitomize modern therapeutic procedures, and a therapeutical index has been added, which should prove of much value to the clinician. The volume consists of 1,860 pages of somewhat small type. It is illustrated in the way usual to such treatises, and naturally contains a mass of information which is universally required by the student or practitioner of medicine or pharmacy. The men who have united to produce this volume assure its trustworthiness.

Lectures on Clinical Psychiatry. By DR. EMIL KRAEPELIN, Professor of Psychiatry in the University of Munich. Authorized translation from the second German edition, pp. 345. Revised and edited by THOMAS JOHNSTON, M.D., Edin., M.R.C.P., London, etc. New York: William Wood & Co. 1906.

The appearance within two years of a second edition of this admirable work of Kraepelin shows plainly the instant and general recognition of its worth. The changes in this edition are few but valuable. They consist mainly of two new lectures (Congenital States of Disease and Morbid Criminals and Vagabonds), and the substitution of more appropriate examples for some used in the first edition. We can add nothing but reiteration of its importance and value to our more extended notice of the first edition of this admirable textbook.

A Textbook of Medical and Pharmaceutical Chemistry. By LEWIS H. BAILEY, B.S., M.D., Ph.D., Professor of Chemistry, Toxicology and Pediatrics in Long Island College Hospital, late Dean and Professor of Organic Chemistry in the Brooklyn College of Pharmacy, etc. Sixth revised edition. Philadelphia: P. Blakiston's Son & Co. 1906.

This edition closely resembles the preceding one. There have been a few changes in the one, particularly in the arrangement of topics, and a number of analytical processes have been left out because this is not a laboratory text-book. The book is essentially a descriptive, general, and inorganic chemistry, although considerable space is devoted to physiological chemistry.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 1, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 and 29 BROMFIELD STREET, BOSTON, MASS.

THE PURGATION OF THERAPEUTICS.

In a paper on "The Medical Profession and the Medical Journals in Relation to Nostrums," read before the Medical Section of the Suffolk District Medical Society, and published in this week's issue of the JOURNAL, Dr. Frank Billings makes this statement: "Primarily the medical profession is to blame for the present extensive use of proprietary medicines, the majority of which are nostrums." The discussion of the subject which follows this initial statement brings with it an arraignment of the medical profession at large, which we are inclined to think the facts do not wholly justify. The entire discussion, now so prominently before the medical profession, and the laity as well, naturally has for its object the elimination of certain abuses which have grown up during the past few years. That these abuses exist no one who has looked into the subject will be inclined to deny; that the best means of preventing them is to make a violent general attack is open to question. It is well, so far as possible, to recognize clearly the abuses and also to do justice to those who are honestly attempting to forward the cause of therapeutics.

Certain points must at once be admitted. Nostrums are bad and should not receive the encouragement of the medical profession; advertising methods are justly open to criticism; they are often extravagant, exaggerated and inexact. This is a natural tendency of all advertising, but no doubt is worthy of special condemnation in matters relating to medical treatment. Furthermore, the attempt to foist unworthy preparations upon the unwary medical profession should be combated. The remedy for this lies with the physicians themselves. On the other hand,

certain demands may rightly be made by the medical profession to which we are inclined to think reputable manufacturing chemists will assent. The essential element in the improvement of the situation is publicity. We should know what we are prescribing, and we should expect advertisers to accede to this reasonable and rational demand.

The contention of which we have heard much of late that the Pharmacopœia contains all the drugs and preparations necessary for the treatment of the sick is a specious argument, and one which, if strictly followed, would retard therapeutic progress. The revisions of the Pharmacopœia are infrequent. Extra-pharmacopœial drugs must be tried if their efficiency is to be determined before receiving recognition in the Pharmacopœia. By this means our rational therapeutics have grown. Many of our most useful drugs, now official, have gone through this period of probation. These general facts, we take it, no reasonable person will dispute. It becomes, therefore, a very questionable indication of the liberality of a physician's therapeutic attitude when he states that he has confined his drug-giving to the preparations contained in the Pharmacopœia. In our opinion it is neither desirable nor possible to limit ourselves in this way. If we do not so limit ourselves, it becomes necessary for the medical profession at large to co-operate with the manufacturing chemists in the enlargement of the scope of our therapeutic efforts. There can be no question that the manufacturing chemists have been of service to the general cause of practical therapeutics. They have co-operated with the medical profession in modifying official drugs to meet certain indications, and in rendering medicine palatable by methods known and acknowledged to be useful by every one. It is absurd to suppose that the physician of the future is going to confine himself to the writing of prescriptions when the ingredients he wishes are already combined by responsible persons in highly palatable and acceptable form. There is reason to believe that the prescription put up by the neighboring apothecary is not always what it purports to be. The remedy, therefore, for the present unfortunate condition of affairs is not wholesale denunciation, but a completer co-operation between physicians and manufacturers, to the end that the manufacturers will be as unwilling to overstep the bounds of propriety as the physician. There is sufficient evidence at hand to show that such a point of view is not chimerical.

Our attitude toward frauds and impositions must be uncompromising, but in this attitude we should take every care not to do an injustice to those who are trying, if they were permitted, to work in harmony with the medical profession and its ideals. The present situation has not been the growth of a day. It is evident that the reformation cannot be accomplished at once. It is a question demanding most careful consideration from every point of view, and if this be given it with calmness of mind, we are optimistic enough to believe that the manifest evils of the present will surely be modified and gradually largely eliminated. The pendulum has swung too far in one direction, and pendulums have the habit of swinging an equal distance in the other.

TREATMENT OF PNEUMONIA BY FRESH AIR.

THE daily press has given wide publicity to a method of treatment of pneumonia by fresh air which is claimed to be new. This matter has been brought forward through articles appearing in medical journals drawing attention to the value and efficiency of liberal fresh air in the care of the disease. In our issue of last week we published a paper from the pen of Dr. W. P. Northrup, of New York, who insists upon fresh, cold air as a rational method of meeting the indications. That there is much reason in this point of view is not to be questioned. It must, however, be recognized that practitioners for many years have employed fresh air in this disease as in others and have insisted that the windows of the sick room should be freely opened, with an open fire where possible. The peculiar efficiency, which is popularly supposed to reside in a tent, we are inclined to think has been somewhat exaggerated. The same results may, no doubt, be attained in a properly aired and ventilated room. The tendency, however, to go to extremes, in this matter as in others, is justified by the extreme difficulty of influencing conservatives toward progress. This present agitation regarding the treatment of pneumonia will prove highly salutary in demonstrating the fact that rational therapeutics may be applied to pneumonia as to tuberculosis and many other diseases, thereby removing prejudice which always stands in the way of progress. Although as yet experience is limited, we have no doubt as cases multiply it will be found that they do as well or better with the liberal supply of fresh air which is now being advocated.

HOSPITAL CARS.

THE refinements of modern railway travel have made necessary libraries and other appurtenances of home life. It is, therefore, a natural development that provision should be made for the care of the sick, and this has been undertaken by the Southern Pacific Railroad. This road has recently completed in San Francisco a car arranged primarily for hospital purposes, but so constructed that it may be converted into an ordinary official or private car. A recent number of the *Railway Age* gives the details of the construction of this car, which is apparently admirably equipped to meet not only the exigencies of illness, but also the comforts of travel. It is planned that when the car is not in use it is to be held at the company's hospital near West Oakland, with a trained nurse and cook, who are to see that it is always in condition for emergency service. Owing to the long distances between stations and hospitals on the Southern Pacific system and consequent delay in getting patients to a hospital, it is proposed to use a special engine to take necessary doctors and hospital equipment to the scene of a wreck. In addition to this car, the road also proposes to build others, arranged and equipped in a similar manner but less elaborately. As a further protection of its patrons, the company is to establish a number of emergency hospitals at remote places along the line. The relative frequency of serious railway accidents and the disabling character of the injuries usually produced render such provisions as the foregoing altogether desirable. No doubt lives might be saved and much suffering obviated were proper facilities immediately at hand to care for the wounded. The usual experience is that medical and surgical aid is not forthcoming and the appliances necessary, even for first aid are not ready at hand. The plan, therefore, of maintaining hospital cars is to be highly commended and should be generally adopted by railroads, particularly in the United States where distances are great and hospital facilities imperfect.

MEDICAL NOTES.

APPOINTMENT OF PROFESSOR VON BERGMANN.

It is announced that Prof. Ernst von Bergmann has been given a life appointment by Emperor William to the upper house of the German Parliament. An honor of the character has never before been conferred upon a member of the medical profession.

QUEEN AMELIE, OF PORTUGAL, HONORARY PRESIDENT. — Queen Amelie, of Portugal, who is a Doctor of Medicine, will be honorary president of the Fifteenth International Medical Congress which convenes in Lisbon on April 19.

THE PHILIPPINE JOURNAL OF SCIENCE. — The first number of the *Philippine Journal of Science*, to which we have already made reference, appears in attractive form and with weighty contents. The general scope of the journal is wide and will publish papers in the domain of several allied sciences. The publication is a continuation of the previous publications of the Bureau of Government Laboratories. This first number contains five articles bearing wholly upon the problems of the tropics. If one may judge from the character of the printing and the admirable half-tone reproductions, the progress of the printer's art in the Philippines has been phenomenal.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, Feb. 28, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 41, scarlatina 13, typhoid fever 10, measles 204, tuberculosis 76, smallpox 0.

The death-rate of the reported deaths for the week ending Feb. 28, 1906, was 21.29.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, Feb. 24, 1906, was 261, against 217 the corresponding week of last year, showing an increase of 44 deaths, and making the death-rate for the week 22.87. Of this number 138 were males and 123 were females; 256 were white and 5 colored; 149 were born in the United States, 106 in foreign countries and 6 unknown; 41 were of American parentage, 180 of foreign parentage and 40 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 59 cases and 6 deaths; scarlatina, 13 cases and no deaths; typhoid fever, 45 cases and 34 deaths; measles, 191 cases and 2 deaths; tuberculosis, 45 cases and 34 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 50, whooping cough 3, heart disease 26, bronchitis 7 and marasmus 5. There were 11 deaths from violent causes. The number of children who died under one year was 41; the number under five years, 63. The number of persons who died over sixty years of age was 63. The deaths in public institutions were 72.

There 3 cases and 1 death reported from cerebrospinal meningitis during the week.

REGULATION OF MEDICINES. — A hearing was held Feb. 27 before the Public Health Committee of the Massachusetts Legislature on several bills which had been presented for the regulation of the sale of various patent and proprietary medicines.

APPOINTMENT OF DR. DAVID D. SCANNELL. — Dr. David D. Scannell has been appointed by Mayor Fitzgerald a member of the Board of Pauper Institutions Trustees to succeed the late Dr. J. B. Cherry. It is peculiarly fitting that a physician should be appointed to this position, inasmuch as the hospital is coming to take a more and more prominent position in relation to the institution at large.

NEW YORK.

MEDICAL EDUCATION IN JAPAN. — On the evening of Feb. 15, Baron Takaki delivered an address on Medical Education in Japan, before the New York Academy of Medicine, and afterwards a reception to him was given by the Fellows of the Academy.

FUND FOR MONTEFIORE HOSPITAL. — The trustees of the Montefiore Hospital and Home for Chronic Invalids have established a fund of \$25,000, the interest on which is to be devoted to the assistance of those who have been cured or permanently relieved in the institution. The patients of the country branch, the Bedford Sanitarium for Consumptives, are included among the beneficiaries of this fund.

GERMAN CHARITY BALL. — The annual German Charity ball, which was given in January, this year, netted the sum of \$13,000, and this has just been divided among nine institutions. The German Hospital and Dispensary receives the largest amount, \$2,300, and each of the others, \$1,450. Among the beneficiaries are St. Mark's Hospital, the West Side German Dispensary and St. Francis' Hospital.

Miscellany.

PROFESSOR MINOT CONCERNING OLD AGE.

In a brilliant address not wholly innocent of paradoxes, Dr. Charles Sedgwick Minot of Harvard told the Academicians of Medicine that old age "begins before birth." This explains, perhaps, the solemn and preterpreadamite gravity

of certain babies. But, however comforting it may look to know that one's old age begins before he begins, there is small consolation in these refinements. Not the beginning need concern anybody. It is the end that is feared, the hour of fading strength, the "hour when the keepers of the house shall tremble, and the strong men shall bow themselves." Old age and death are as natural as life, but they are a part which it takes a great deal of religious philosophy and quotations from the poets to adorn.

As if old age could not come fast enough, various doctors are now trying to show that it begins earlier than it used to. Dr. Minot asserts that "permanent fatigue" starts at about forty. Everybody knows plenty of persons who were born permanently fatigued; probably their permanent fatigue began before they did. "Permanent fatigue" as a mental characteristic has no necessary connection with old age.

Let the fathers and mothers of venerable monthlings and yearlings read and perpend these words of Dr. Minot's:

"The percentage of growth is greatest in the first month after birth, and steadily decreases from then. In other words, man ages faster in the first year of his birth than ever after. A child in its first year learns more than it ever acquires in an after year. The things we learn afterward come harder each year, until the time comes when man can acquire no more and his power of originating ceases. His usefulness, while not altogether done, is on the wane."

After all, there is healing in this. The child is older than his father. Merlin must have been a real character. And everybody over twelve months is a dullard and on the wane.

With the progress of the suns will not authority go with wisdom? The yearlings are the quickest, the least degenerate. Theirs be the sceptre and authority.

Dr. Minot says that the lower orders of animal life never die save by accident. Curiously enough, among the lower orders of human life, the savage and primitive folk it is or was believed that nobody died save by the design and witchcraft of an enemy. *New York Sun.*

Musser, Philadelphia; Dr. Frank Billings, Chicago; Dr. W. W. Keen, Philadelphia; Dr. Nicolas Senn, Chicago, Dr. F. C. Shattuck, Boston; Dr. R. Matas, New Orleans; Dr. Albert Vander Veer, Albany. Dr. Walter G. Chase, Boston; Dr. E. DeWitt Connell, Portland, Ore.; Dr. Ramon Gutierrez, New York City.

At the Congress an orator will represent each country in delivering an address or oration before the assembled sections of the meeting. Dr. Nicolas Senn will represent this country as orator, and will deliver an address on "The International Study of Carcinoma."

Information regarding the scientific part of the Congress can be obtained by addressing the secretary of the American Committee. Information concerning transportation to and from the Congress can be obtained from Dr. Chas. Wood Fassett, St. Joseph, Mo., who is in charge of the American party.

RESOLUTIONS ON THE DEATH OF DR. JOHN I. FRENCH.

By the death of Dr. John I. French, of Winchester, the Middlesex East District of the Massachusetts Medical Society has to mourn for the loss of one who was an active worker for the advancement of medical science, and who was deeply interested in the welfare of the society and of its members. Taken from us when he was approaching that period in his life when its activities should be at their best, the announcement of his death came as a sudden blow to all but his more intimate friends. In him we have lost a man of moral courage, a kind and sympathetic friend and a genial companion.

Be it resolved: That the Middlesex East District of the Massachusetts Medical Society express its heartfelt sympathy to the family of the late Dr. John I. French.

C. W. HARLOW, M.D.,
Secretary.

Correspondence.

INTERNATIONAL MEDICAL CONGRESS.

Mr. Editor. Kindly announce through your columns that the organization of the American party to the Congress is nearly complete and hotel reservations in Lisbon will be closed in a few days. Those who contemplate joining the party should send in their names within the next ten days in order to insure good hotel reservations. Those who are familiar with hotel conditions in Portugal will appreciate the importance of early action.

For the information of your readers who have not received the regular *Traveler*, remember that the American party will sail from New York on April 7 on the North German Lloyd steamship, *Koenig Albert*. The rate of sailing and expenses will be \$300 per individual. Money due to be paid in order to Europe or to return to other countries must have all arrangements made to suit the place of departure and return. It is suggested that the party should be made at once, however, as hotel and railway trip can be arranged later. Board of travel and itinerary may be obtained through:

Dr. Chas. Wood Fassett,
St. Joseph, Mo.

INTERNATIONAL MEDICAL CONGRESS.

Dr. RAMON GUTIERREZ, secretary of the American Committee of the International Medical Congress at Lisbon, informs us that the arrangements of the American National Committee for the International Medical Congress have now been fully made. The gentlemen who have planned to present papers at the Congress should at once send abstracts of their papers to the secretary-general of the Congress, Dr. Miguel Bonilla, Madrid. These abstracts should be very short and should simply outline the scope of the paper. The official delegates from this country have been appointed by the Secretary of State, Hon. Elihu Root, and are as follows:

Dr. I. L. McMurtry, Louisville, Dr. John H.

RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, FEB. 17, 1906.

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING FEBRUARY 21, 1906.

ROSENAU, M. J., passed assistant surgeon. Detailed to attend meeting of Committee of American Bacteriologists in New York, N. Y., Feb. 24, 1906, relative to the standardization of tetanus antitoxic sera. Feb. 19, 1906.

MOORE, DUNLOP, passed assistant surgeon. Relieved from duty at Yokohama, Japan, and directed to proceed to Honolulu, Hawaii, reporting to chief quarantine officer for duty. Feb. 14, 1906.

CURRIE, D. H., passed assistant surgeon. Department letter of July 27, 1905, amended so as to grant Passed Assistant Surgeon Currie twenty-one days' leave of absence from July 18, 1905, instead of 2 months. Feb. 17, 1906.

BERKHAETER, J. T., passed assistant surgeon. Granted seven days' extension leave of absence from Feb. 24, 1906. Feb. 20, 1906.

FRISSELL, C. M., acting assistant surgeon. Granted twenty days' leave of absence from Feb. 14, 1906. Feb. 16, 1906.

HALLET, E. B., acting assistant surgeon. Granted five days' leave of absence from Feb. 19, 1906. Feb. 19, 1906.

TOWNSEND, F., acting assistant surgeon. Granted seven days' leave of absence from Feb. 21, 1906. Feb. 19, 1906.

WALSHROUS, M., pharmacist. Department letter of Jan. 30, 1906, amended so as to grant Pharmacist Walrous thirty days' leave of absence from Feb. 8, 1906, instead of Feb. 15, 1906. Feb. 16, 1906.

BOARD CONVENED.

Board of officers convened to meet at the Bureau, Feb. 27, 1906, for the purpose of making physical examination of an officer of the Revenue-Cutter Service. Detail for the Board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon J. W. Trask, recorder.

APPOINTMENT.

DR. ALBERT J. NUTE appointed acting assistant surgeon for duty at Port Huron, Michigan. Feb. 20, 1906.

CHANGES IN THE MEDICAL CORPS U. S. NAVY FOR THE WEEK ENDING FEBRUARY 24, 1906.

F. W. TYRRE, acting assistant surgeon. Detached from the Naval Training Station, San Francisco, Cal., and ordered to the Naval Recruiting Station, Kansas City, Mo.

SOCIETY NOTICE.

AMERICAN MEDICAL ASSOCIATION CHORUS. — I have been asked to announce to eighty voices a chorus of physicians (who have sung together for some years past at the annual dinner of the Massachusetts Medical Society) in order that we may furnish some music at the President's Reception during the coming meeting of the American Medical Association in June, 5-8. We have now forty-five names on our chorus list. We must have five or six rehearsals between now and June. Anyone knowing of any good singers in the profession (graduates or undergraduates) will please suggest names (their own or others') to

RICHARD C. CABOT, M.D.,
190 Marlboro St., Boston.

APPOINTMENT.

DR. CHARLES SEDGWICK MINOT has been appointed James Stillman Professor of comparative anatomy in the Harvard Medical School.

RECENT DEATHS.

SAMUEL DOOLITTLE BROOKS, M.D., M.M.S.S., died in Springfield, Feb. 26, 1906, aged eighty-nine years.

DR. H. MARTIN BRACE, of Perth Amboy, N. J., died on Feb. 20. He was born at Catskill, N. Y., in 1859, and practised in Port Jervis until 1892. At the time of his death he was Mayor of Perth Amboy and Vice-Commodore of the Raritan Yacht Club.

BOOKS AND PAMPHLETS RECEIVED.

Biographic Clinics. Volume III. Essays Concerning the Influence of Visual Function Pathologic and Physiologic upon the Health of Patients. By George M. Gould, M.D. Illustrated. Philadelphia: P. Blackiston's Son & Co. 1905.

Zur Therapie der funktionellen Enuresis. Von Dr. med. Theodor Zangger. Reprint.

A New View of Sleep. By A. K. Bond, M.D. Reprint.

How to Palpate a Movable Kidney. By Charles D. Aaron, M.D. Reprint.

Why Surgical Fixation of a Movable Kidney will not Relieve Dyspeptic and Nervous Symptoms. By Charles D. Aaron, M.D. Reprint.

Pathogenic Micro-Organisms, including Bacteria and Protozoa. A Practical Manual for Students, Physicians and Health Officers. By William Hallock Park, M.D., assisted by Anna W. Williams, M. D. Second edition, enlarged and thoroughly revised. Illustrated. New York and Philadelphia: Lea Brothers & Co. 1905.

The Blues (Splanchnic Neurasthenia). Causes and Cure. By Albert Abrams, A.M., M.D. (Heidelberg), F.R.M.S. Second edition, enlarged. Illustrated. New York: E. B. Treat & Co. 1905.

The Medical Record Visiting List or Physicians' Diary for 1906. New revised edition. New York: William Wood & Co.

Mines de Houille rendues Réfractaires à l'Ankylostome par des Eaux Sulfatées de Filtration. Par Le Dr. A. Manouvrier. Paris. 1905.

Twelfth Annual Report of the Medical Examining Board to the Members of the Connecticut Medical Society for the Year ending July, 1905.

Lectures on Auto-Intoxication in Disease or Self-Poisoning of the Individual. By Ch. Bouchard. Translated with a preface and new chapters added, by Thomas Oliver, M.A., M.D., F.R.C.P. Second revised edition. Philadelphia: F. A. Davis Co. 1906.

Contraction of the Visual Field. A Symptom of Anesthesia of the Retina in Children. By L. Webster Fox, A.M., M.D. Reprint.

Ablepharia Partialis of Upper Eyelids. By L. Webster Fox, A.M., M.D. Reprint.

Ophthalmic Conditions and School Hygiene. By L. Webster Fox, A.M., M.D. Reprint.

Ocular Injuries and their Prognosis. By L. Webster Fox, A.M., M.D. Reprint.

University of California Publications. Physiology. On Chemical Methods by which the Eggs of a Mollusc (Lottia Gigantea) can be caused to become mature. By Jacques Lock. Life Insurance: The Abuses and the Remedies. By Louis D. Brandeis. Boston. 1905.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., assisted by H. R. M. Landis, M.D. Philadelphia and New York: Lea Brothers & Co. Dec. 1, 1905.

Address.

THE VALUE OF LABORATORY METHODS TO THE COUNTRY PRACTITIONER.*

BY J. B. COWAN, M.D., DANVILLE, KY.

It has seemed to me that in the last few months it is almost impossible to pick up a medical periodical or magazine which does not contain a more or less extensive discussion of the great value of the laboratory. We read long articles devoted to a consideration of the progress made in perfecting the efficiency of laboratory technique. There is, first, the enormous field of original research. Investigations of every sort and description are being conducted everywhere in the world for the furtherance of exact methods in the science of medicine. As the results of these researches become verified they are classed as recognized diagnostic methods—methods which are available in establishing accurate diagnoses.

At present, the whole tendency in medicine is an earnest effort to attain the highest possible degree of accuracy. It is evidenced in the desire to discard and to weed out those methods which depended upon empiricism, and the mythical, vague and mysterious quality called intuition, sometimes called (for most grossly mis-called) "common sense." There are, of course, many facts which long experience has verified, but which are based upon pure empiricism. Such of these as are proven to be facts are of immense value and will be accepted as such, but will always remain the subject of continued investigation until they become solved problems. But there are too many conclusions based upon propositions whose sole foundation is tradition, a tradition which has had its origin, in many instances, in the hurried publication of unverified results of the imperfect work of some enthusiast.

There are, then, two classes of empirical facts. One, which, although we do not know its details of cause, *modus operandi* and effects, yet we do know that long experience and satisfactory observation has established it beyond the slightest doubt. Facts of this class must and will remain, and will be relied upon until exact demonstration proves either that they are false, or establishes and explains them, and by so doing transfers them from the domain of empiricism. The other class of facts are those empirically accepted, but which lack the overwhelming testimony of time and experience; these the tendency to accuracy would discard.

There is also much discussion in our periodicals of such questions as the relative value of the scientist and the practical physician. I have recently read an article entitled "Scientist versus Physician." Such articles seem to have their origin in the doubt as to whether the physician is, or can be, a scientist. But really it is an expression of the question, "Is the laboratory worker doing more for medicine than the clinician?"

There can be no alienation of laboratory from clinical methods; they are so interdependent as to be incapable of separate existence. Within my own limited time spent inside the medical body I have heard much ridicule cast at the science of bacteriology and laboratory methods in general. I have heard one gentleman repeatedly say that he preferred to rely upon his common sense than to be "fooling" with such things. In the present time there can be no excuse for the continuation of such opinions.

The medical periodical comes to every man's office, and he cannot fail to keep himself in touch with something of the present development of medical science if he reads his periodicals at all. It does not require a knowledge of the technique to be convinced of the value of the laboratory. If our common sense friend will read his periodicals he will learn that reputable men whose testimony must be believed are accomplishing results "not dreamed of in his philosophy" of pseudo-common sense. Even if he knows nothing in detail of the use of the microscope, he is forced to know that its value to medicine can never be calculated. It is not to be expected that a man can keep so well up in all the many departments of medicine as to be able to take his place as a specialist in its every branch, but unless he does read enough to know something of what is being done in these branches he is already so far behind the procession that he will never catch up to it.

The great search after truth in the science of medicine is bringing about such a specialization of its work that no one man can do more than keep himself posted upon the more important results of these several branches. In our large cities the matter has so divided itself among numerous men that every man has at his disposal and for his help the skill and peculiar knowledge of some one man working solely in a separate branch. The amount of value of this combination cannot be over-estimated. Even in our smaller cities the division of the work has advanced to quite a degree of helpfulness by developing efficiency of those men who can devote their time to specializing. The more that the work and investigation in the medical sciences is divided up, the more time there will be devoted to individual problems. And each problem will, by this natural selection, be assured to those men whose acquaintance and experience with it make them peculiarly fitted to deal with its intricacies.

But this does not mean the alienation of the laboratory and the clinic. For without the clinic where would come the problems for solution, or the material for experimentation? In fact, without the clinic there would be no need for any such experiment at all. And where else could I find that supreme test of the correctness of laboratory research and consequent suggestions seen at the "bed side"? But the specialization of medicine means more than the separation into the abstract investigator and the concrete dealer with individual cases. It means that the laboratory

*The address of the retiring president of the Boyle County Medical Society. Read at Danville, Ky., December, 1905.

methods must be evolved by one set of men and must be judged of by another set. The clinician will always be the man to have the last "say" upon medical questions. The true value of any medical discovery is not to be estimated by its scientific accuracy nor by laboratory methods, but always depends upon its value to the clinician at the bed side, in other words, to the ultimate object of our calling — to sick and suffering man.

We, who live in the country, have little time to specialize. It is incumbent upon us all to prepare ourselves to the best of our abilities, and then — not to sit down and let the years pass us by and leave us nothing out of the great accumulation of their knowledge, but to keep on preparing ourselves until the last.

A man comes out of a medical school, provided his opportunities have been good, fairly well equipped to begin to acquire his education. And this education can only be secured by continually keeping up as well as he can. If he lives in a large city he may keep up in his own branch and depend upon the other fellow for help in the others.

But what of us who live in the country? Simply because the great mass of new matter turned out year by year is too much for any one intellect is no reason why the country doctor should not show in this particular, as he does in all others, evidence of ability to surmount great obstacles.

The practising city physician is, by reason of his environment, stimulated to mental effort. His surroundings, his contact with thinking men of other professions than his own, but more especially, his close association with the earnest, thinking men of his own calling, are constant spurs to bring out all that is best in him. Nothing is truer than the fact that thought begets thought. The country physician, on the other hand, is isolated; he must meet, single-handed and alone, many of the exigencies and unravel many of the problems which are presented to his more fortunately placed city brother. He lacks the great advantages of large clinics, which offer the city practitioner such great opportunities, not only for observing a great variety of cases and a great many cases of these varieties, but it gives him the opportunity for putting into practice the many suggestions of which he reads. And yet the really important feature of the large clinic is not in the above enumeration, but, it seems to me, lies in the great opportunity for training, under the very best possible circumstances, the powers of observation; for developing to their highest possible attainments all the faculties.

The association with a body of earnest, hard-working and high-minded colleagues at the same time serves as a stimulus to good work and keeps a man from dropping into routine methods.

The country practitioner lacks the advantages of the clinic; in the more isolated regions he is alone and has no associate with whom he may share responsibilities, or from whom he may derive inspiration. In the towns we do have fraternal relations, which, in the writer's judg-

ment, are capable of producing more valuable results than they do now.

The meetings of the country and district societies show an appalling lack of interest. Our own county organization is in no way different from others; for the president of one of our adjoining county societies tells me that it is rare to have a quorum present at their monthly meetings. We do not get together and spend pleasant and profitable evenings simply on account of a state of lethargy which has overtaken us. And I am free to say that I believe this chilling lack of interest is due to the feeling that we have nothing of interest to talk about.

We feel that the old, old story of typhoid fever and appendicitis has been gone over again and again until the subject is threadbare. We feel that we have said all that we know how to say upon pneumonias, pleurisies and obstetrics, and all of these common-place topics. It is not that the diseases have changed and modified with the passing of years. They are the same entities as years and years ago, but the change has come from the continued advance putting new interpretations upon them; lending their thread-bare topics the keenest of new interest.

And I challenge any member to say that it is impossible to introduce into our county societies the same new features, in kind, if not in degree, as are introduced into the great medical meetings in our large cities. There is not a man among us who does not have a large number of cases every year which, if he would apply to them the discoveries of the newer pathology and methods of investigation, would yield a big return, not only in the interest of the individual case and cases of its kind, but in every other case; an interest arising from more accurate observation.

It is impossible, from the very nature of the circumstances, that the country practitioner can develop himself into a specialist in every branch of the great domain of medical science. But the limits of his progress and of his improvement are to be determined solely by the amount of earnest, conscientious effort devoted to it. It may be impossible that he should invoke immediately the perfected efficiency secured by the rapidly changing methods of investigation. It may be that he has got to be always a little behind, but just how far he will be behind depends upon himself. If he dismisses the use of laboratory methods in their highest development he will never use them at all. But if he will diligently set himself to apply such methods and to adapt them to his changed conditions, conditions modified by his circumstances, and give his whole-souled attention to this adaptation, the degree of proficiency to be attained will be limited by the amount of endeavor. It is, perhaps, not possible, at least not probable, that he will do much to *advance* the science of medicine; but it is possible that he can, if he tries, prevent the procession from leaving him behind. And the recompense for such effort is to be found in the endeavor itself.

If we say it is impossible that he should con-

been so simplified as to be within the reach of the general practitioner. I believe, however, that in case the country practitioner gets "rusty" on any of these matters he can almost take a post-graduate course in his own laboratory by sending to some of the city laboratories and securing mounted specimen. A careful résumé of any subject with such specimens before him is of immense value.

There are, I believe, many things in the laboratory which must always be done by the laboratory expert, the man who devotes his whole time to this subject, who is doing the same thing day after day and, perforce, becomes unusually proficient in it. To him, I think, must belong many investigations in pathological histology. I do not think that the average country practitioner can have sufficient material to keep him up in this branch. The examination of uterine scrapings, of the stomach contents for cancer cells, is more difficult than the bacteriological examinations, but, again, these depend entirely upon the persistent effort of the individual, and this makes the only limitation.

The value of the laboratory to the country doctor is, then, to be summed up in the following conclusions:

(1) Its value in dollars and cents.

Any agency which will increase a business along profitable lines is a valuable asset. In the country community more than elsewhere the results of the physician are discussed by the laity. His successes and his failures are considered and compared with those of his competitors. The intelligent layman can and will distinguish the difference between the authoritative and forcible statements made by the physician who has applied to the case under investigation accurate, scientific methods and the hesitating, ambiguous expressions of the man who has jumped to conclusions. The right sort of self-confidence, arising from accurate knowledge, begets a confidence in the patient which is the physician's most valuable asset. Such confidence is bound to increase the amount of his business and improve the character of his clientèle.

(2) Its value to his patients.

Anything which increases his efficiency and contributes to his professional attainments must redound to the good of his patients. The patients of the country doctor are as much isolated as he, and must depend wholly upon him; he is, therefore, in duty bound to give them a compensation for this absolute dependence. But a consideration of the value to the patient implies a doubt of its value in general, which has been settled beyond discussion.

(3) Its value to himself.

And here is to be found a value peculiar to the country doctor. He must find within himself his inspiration to good work. As has already been said, he feels his isolation deeply, and envies his city brother his constant association with earnest, thinking men of his own calling. It seems to me that the laboratory offers to us who live in the country our only means of keeping up with

the times and our only stimulant to persistent effort toward self-improvement. The country physician, after a long, cold drive, is too often prone to rush through his investigation of a case, jump to a tentative diagnosis, and apply expectant treatment, blindly depending upon the powers of nature. It may be urged that the country physician cannot systematize his time, and, therefore, lacks opportunity for laboratory work. This may be answered by saying that there is no class of men doing more work for which they receive no return, either in money or gratitude, than the country physician. And if he will do less work of a certain sort in order that he may do a smaller amount of work of a better sort he will be more worthy of compensation. There can be no question that patients are willing to pay a physician, in some measure, in proportion to his ability. If, therefore, he increases his ability by the use of the laboratory he can make his time so spent pay him a return in his greater ability, represented by an improvement in the size of his fees.

The country physician is, too often, an empiricist. He, perhaps, more often than any one else, fails to distinguish between *post hoc* and *propter hoc*. This propensity is evidenced in the testimonial "literature" circulated by the proprietary nostrum. This literature often forms the major part of his reading, and is, not infrequently, his whole library so far, at any rate, as his therapeutics is concerned. The desire for accuracy, born of the laboratory, prompts him to discard such courses of information and tends to stimulate him to more profitable reading.

If he is engaged in the application of laboratory methods he is very apt to keep himself posted and keep in touch with his profession.

The chief value in this regard, as in all others requiring mental and intellectual effort, comes in the improvement of the man himself; and, as was said before, the compensation for such endeavor is in the effort itself.

Massachusetts General Hospital.

CLINICAL MEETING, JAN. 26, 1906.

THE VALUE OF VIRCHOW'S SMOOTH ATROPHY OF THE BASE OF THE TONGUE IN THE DIAGNOSIS OF SYPHILIS.*

BY NATHANIEL BOWDITCH POTTER, M.D., NEW YORK.
Visiting Physician to the City Hospital and to the French Hospital;
Consulting Physician to the Central Islip State Hospital;
Instructor in Medicine, Columbia University.

My friend and colleague, Dr. Horst Oertel, pathologist to the City Hospital, called my attention to this sign two years ago, while performing an autopsy upon a patient who died in my wards, with the clinical picture of primary anemia. The blood examination in this case was not typical, and our ante-mortem diagnosis was left in doubt. Dr. Oertel demonstrated to us a marked atrophy of the base of the tongue, decided that

BY NATHANIEL BOWDITCH POTTER, M.D., NEW YORK.
*Visiting Physician to the City Hospital and to the French Hospital;
Consulting Physician to the Central Islip State Hospital;
Instructor in Medicine, Columbia University.*

My friend and colleague, Dr. Horst Oertel, pathologist to the City Hospital, called my attention to this sign two years ago, while performing an autopsy upon a patient who died in my wards, with the clinical picture of primary anemia. The blood examination in this case was not typical, and our ante-mortem diagnosis was left in doubt. Dr. Oertel demonstrated to us a marked atrophy of the base of the tongue, decided that

* Read in part at the Jan. 26 Clinical Meeting of the Medical Board of the Massachusetts General Hospital.

the patient had, therefore, had syphilis, and considered that the anemia was probably secondary to the luetic infection.

This interested me to endeavor to determine how useful this sign may be in the diagnosis of syphilis during life. Before summarizing the results of my investigation, a résumé of the chief articles upon the subject will be of interest.

Lewin and Heller¹ state that Virchow repeatedly emphasized the value of the atrophy of the "Zungenbalgdrüsen" (follicular glands) in the diagnosis of late syphilis, and that he believed there was a causal relation between the two. His teaching descended by word of mouth among pathologists. The oldest preparation in the Institute is dated 1863. Lewin himself spoke of it as early as 1879.² These two authors examined the protocol records of 6,583 autopsies and found anatomically confirmed syphilis in 3% of them, three fourths of which were acquired constitutional lues. They found a smooth atrophy of the base of the tongue in 103 of the 6,583 cases (1.5%), and of these 103 cases definite evidence of syphilis occurred in 69%. So large a percentage supported the assumption of an etiological connection between the smooth atrophy and syphilis. They considered the confirmation of smooth atrophy a more useful sign of syphilis to the clinician than to the syphilographer, because most cases of syphilis of the internal organs come under the care of the former. They enumerated 64 cases from the medical clinic, 9 from the surgical clinic, 14 from the psychiatric and nerve clinic and 4 from the gynecological clinic, a total of 91, as against 5 patients from the syphilitic clinic. In an analysis of 71 cases in which this sign was observed, no special frequency of any other diseases could be detected. In an analysis of the patients' ages in 87 cases,

87

In other words, 62% of the patients were over forty years old. They found that women possess this sign rather more frequently than men, and explain it upon the ground that primary and secondary syphilis is so often unrecognized in women, and they are later affected with so-called tertiary symptoms. They consider that the atrophy persists longer than most of the other appearances of syphilis, and that it is probably irreparable. They believe that an interstitial inflammation produces an actual smooth atrophy, whereas an ulcerous or gummatus process produces a cicatricial condition. They describe the microscopical appearance of the upper layers at the base of a normal tongue, and discuss Kelliker's account of the lymphoid tissue surrounding the follicular glands, and the arrangement of

lymphoid tissue in the shape of masses or strands, the whole forming a so-called lingual tonsil.

In detailing the appearances of the atrophied tongue, they mention the occurrence of a secondary hyperplasia or compensatory process and of marked turgidity, small hemorrhages, collections of leucocytes, cloudy swelling, — all of some importance in understanding the smooth atrophy. Then follows a description of the follicular glands in a normal tongue. In a sagittal section of the normal tongue from the angle of the circumvate papilla to the epiglottis, they found that there were normally 5 to 12 glands, whereas if this atrophy was present, only 1 to 3 could be discovered. The glands normally had a diameter of 2 to 4 mm., but in the atrophy they were frequently only 1 mm. in diameter, or oftentimes only a little collection of round cells. In many cases, in spite of the disappearance of numerous glands, there was a compensatory hypertrophy of others. They attempt to explain the process as follows: The glandular substance is injured by the immigration or new formation of syphilitic tissue cells within their structure. The new growth crowds aside the original tissue, but the cells soon die and are cast off. Individual glands become smaller or disappear. The process acts interstitially without the formation of gumma or ulcers and actually without real scar formation. Or again that a syphilitic endarteritis precedes, and so diminishes the nutrition to the glands.

They measured the adenoid tissue in normal and atrophied tongues, and found that the former contained five to seven times as much adenoid as the atrophied. They also mention the congested appearance of the blood vessels observed in some cases, and attributed it to a stasis, caused perhaps by the atrophy. They found the mucous membrane usually one fifth the normal thickness, and noted other differences as well. In the clinical examination they depended largely upon palpation, and emphasized the importance of estimating the number, distribution, consistency and size of the glands. They do not lay much stress upon the laryngoscopic examination.

They examined about 300 individuals to determine whether Seifert's statement that 50% to 60% of all patients with specific lesions of the buccal mucous membrane exhibited erosion, aphthae, plaques, or ulcers upon the base of the tongue, and found such lesions in only 34%.

Then follows a detailed description of 14 cases of smooth atrophy of the base of the tongue in connection with syphilis. They were derived chiefly from Lewin's private practice.

They consider that three types of the atrophy can be distinguished. In the first, the entire surface of the tongue is affected, and the normal thickness of the tongue is reduced to one half the normal. In the second, the process of a few years' duration has not advanced to a stage of the tongue, but the entire base of the tongue.

The atrophied tongue plate is shown in Plate I, and microscopical appearance of the tongue in Plate IV and D.

¹Virchow's Archiv. 1880, 4, 1. The atrophie der Zungenbalgdrüsen und die Verhältnisse der Zungenpapillen.

²Ueber pharyngeale Syphilis.

Otto Seifert of Würzburg, in an article, "Ueber Syphilis der Zungentonsille,"² reviews the literature upon syphilis of the lingual tonsil. Most of the articles refer to the occurrence of secondary appearances or of gummata; but he also mentions Lewin's division of syphilis of the lingual tonsil into three types: (1) broad condyloma, (2) gummata, (3) atrophy. He cites 71 cases of syphilis which he examined from the first of January to the first of November, 1892. These cases occurred in the syphilitic wards of the Julius Hospital, in his ambulatory clinic for nose, throat and laryngeal affections and in his own private practice. Ten (3 male and 7 female) of these were affected with a late form, 6 with acquired and 4 with hereditary syphilis. He was unable to determine an atrophy of the "zungenbalgdrüsen" in any of the ten. In some of them the glands were even hyperplastic; also among the cases of hereditary syphilis he found some with hypertrophic lingual tonsils. He mentions two of Lewin's attempts to prove that the atrophy of the lingual tonsil is diagnostic of syphilis.⁴

In a second article,⁵ five years later, Seifert reviews the literature of syphilis of the lingual tonsil more thoroughly than in the preceding, and then discusses the value of Virchow's smooth atrophy of the base of the tongue in the diagnosis of syphilis. Lewin, he says, learned to recognize the sign from Virchow's lectures, and first called attention to it in 1879 and again in 1891.⁶

In a doubtful case of Goldzieher, this sign was utilized for the purpose of diagnosis, again in a gummata of the forehead.⁷ Later on, Lewin considered the absence of this sign argued against the syphilitic origin of a case with spinal cord disease.⁸ He next demonstrated the sign in a case of gummata of the tongue,⁹ and again¹⁰ in an obscure case of scar formation of the abdominal wall. He cited 3 other cases,¹¹ one of which Lassar diagnosed as a malignant tumor of the pharynx. In another case Lewin found in addition to the atrophy of the glands an hypertrophy in some of them.¹² Heller¹³ based the diagnosis of a doubtful case upon this sign. Hansemann found a smooth atrophy at the base of the tongue in a case of puerperal sepsis.

Sandmann¹⁴ demonstrated that this atrophy is by no means so frequently found as autopsy records seem to show. Michael¹⁵ found a similar appearance in many old people without a suspicion of syphilis, and Mraček¹⁶ is of the opinion that Lewin has exaggerated its importance and clinical value. Seifert reminds the reader that in 10 cases of late syphilis mentioned in his former article, he was unable to find an atrophy in any

of them; he then adds a table of 12 other cases of late syphilis which he examined, in none of which could he find a smooth atrophy of the lingual tonsil, and in 4 of them he was able to demonstrate an excessive hypertrophy, and therefore concluded from these 18 carefully examined cases that this atrophy is by no means a valuable sign for acquired syphilis.

In 2 cases of hereditary syphilis, Schotz¹⁷ found the glands decidedly thickened.

Strauss¹⁸ does not mention the lingual tonsil.

Skladny¹⁹ in 24 cases of late hereditary syphilis, found 20 with an atrophy of the lingual tonsil. Hellman²⁰ is apparently of the same opinion, since in case of doubtful syphilitic caries, he considered the smoothness of the base of the tongue as a sure sign of syphilis.

Seifert mentions again the 4 cases of hereditary syphilis with quite marked hypertrophy of the lingual tonsil, and adds 4 more cases, 3 of which showed a lingual tonsil of normal size and free from scars. In the third, the lingual tonsil was hyperplastic on both sides and scarred in the middle; he therefore objects to Skladny's positive statement that an atrophy of the lingual tonsil is always a sign of late hereditary syphilis.

Lesser²¹ mentions Virchow's interest in the sign; that it was overlooked by clinicians until the publication of Lewin and Heller's paper; he describes the opposing views of Seifert and others and explains why the sign fell into disrepute. He then attempts to estimate its value by examining the sections from Professor Langerhan's autopsy material. He avoids some of the sources of error which occurred in Lewin and Heller's paper. In many of their cases the neck organs were not examined; in others the prosector did not recognize or appreciate the value of the sign; in others some of the prosectors took the history sheet's statement of the presence or absence of syphilis as being correct, and in still others, the diagnosis of syphilis was made directly from the presence of the sign. In his series of cases, Lesser considers syphilis to be demonstrated only (1) in the presence of an actual specific exantheme (condylomata or gummata); (2) from the existence of scars upon the skin, the mucous membranes or the bones, which by their pigmented appearance at the periphery, their location, their grouping or their configuration (circular in crescents) are diagnostic; or (3) from interstitial growths in internal organs, perhaps precursors of gummata.

Although nothing is especially characteristic of these interstitial growths, unless they are retrograde, he considers their locations important, *e. g.*, orchitis interstitialis, or their grouping, as, *e. g.*, in the liver, or sometimes their selection, such as interstitial inflammation in several organs, kidney, liver, myocardium, etc. He does not believe Lewin's three clinical stages are helpful, nor does he think they express the essential

¹⁵ Nothmann, spec. Pathol. u. Therapie, xvi, Bd., p. 261.

characteristic of the condition which is the indurated feeling, present in all three of the stages. He regards the thickening of the adenoid tissue to be primary, and the atrophy of the glands secondary to this induration. He thinks a better term would be "glossitis levis posterior," the glossitis expressing the inflammatory nature, the levis the smooth effect produced. He considers palpation to be the best clinical method, and that the laryngoscopic examination should only be used as a control.

In examining the autopsy records of the Moabit-Krankenhaus from 1896 to 1902, he found 166 cases with atrophie levis basis linguae, in which 73 (44%) syphilis was demonstrated anatomically, 17 with gummata, 2 with condylomata, 23 with diagnostic scars on the sexual organs, mucous membranes or skin, 21 with a diagnostic interstitial inflammation in the internal organs. These were all in acquired syphilis.

In hereditary syphilis, Lesser cites Skladny's figures. The latter examined 24 cases of interstitial keratitis in large children and found the sign positive in 20. Other observers have not confirmed his results. The writer then critically examined the percentages quoted by Lewin and Heller and by himself. He considers the sign to be the result of a primary interstitial process similar to a syphilitic hepatitis and not to be preceded by gummata. Of his 166 cases, only 13 showed the typical scarred tongue which we see as a result of a gummatus process. He found no preponderance of females as Lewin did, nor any evidence of a contributing cause in the use of tobacco or alcohol. It occurred at all ages, although he was unable to ascertain any definite time after infection. He found the sign in 21.6% of syphilis with definite tertiary lesions, so that he concluded that the coincidence of glossitis levis and tertiary syphilis is rare, probably because the latter develops much before the former. Hence the rarity of the affection in syphilitic clinics. He expresses surprise at Serfert and Goldschmidt's negative results. He considers the sign very much more important for the clinician than for the syphilographer.

The results of my investigations are as follows:

Source of the material. The patients were selected partly by choice of the internists, partly at random from the eight medical wards at the New York City Hospital, rather a large percentage of them with the history or physical signs of an old syphilitic infection. Most of the remainder were selected by the resident physicians at the Central Islip State Hospital, chiefly from among the parietics or among inmates known to be old syphilis. A few control cases were interpolated to make the test more open. Various other sources furnished the remaining cases.

Method of examination. Some seventy old cases were examined visually with the aid of a laryngeal mirror. This attempt convinced me that the sign could not be appreciated by sight. These cases are not included in the list.

Palpation proved more successful. The patient was asked to protrude the tongue as far as possible; the examiner grasped it in his left hand

with a piece of gauze or a soft towel, and then carefully inserted the index finger of his right hand along the dorsum of the tongue until he reached the circumvallate papillae; then the territory behind the triangle of papillae was explored with very gentle palpation.

A pair of thin rubber gloves or a rubber cot to protect the index finger was employed in many instances. Neither interfere with the result. If the examiner is careful to avoid touching the uvula or the back of the pharynx, and if the patient submits to the momentary discomfort, very little difficulty ensues. I did not find the test caused any more discomfort than the laryngeal mirror. Depending upon the patient's acquiescence and self-control, the back of the tongue is hard, rigid and contracted, or soft, flexible and relaxed. The contrast between the firm, flattened, smoothed, hardened mucous membrane, sparsely studded with small, shot-like glands, both mucous membrane and glands supported upon a yielding cushion of muscle can be made out very much more distinctly than if a similar condition is embedded in a firm, plaster-of-paris-like contracted tongue.

Classification. I was unable to follow Lewin and Heller's classification into three stages. Although a sharp distinction is plain between the soft, velvety, cushion-like adenoid tissue at the base of a normal tongue, and the firm, hard, smooth base in a markedly atrophic tongue with a few shot-like glands, so many cases presented variations that I found it convenient to subdivide my series into: *Negative cases*, those in which the base of the tongue was perfectly normal; *doubtful cases*, those in which there was some hardening, either of glands or mucous membrane, one or both, or some diminution of their number or size; *probable cases*, those in which some or all of these points were more striking; and finally, *positive cases*, those in which the atrophy was very marked.

| | Below 21 | | 1 to 50 | | Above 50 | | Total | |
|----------|----------|----|---------|----|----------|----|-------|----|
| | A* | B* | A | B | A | B | A | B |
| Negative | 17 | 0 | 27 | 1 | 1 | 0 | 45 | 1 |
| Doubtful | 12 | 3 | 13 | 15 | 10 | 17 | 35 | 32 |
| Probable | 4 | 1 | 20 | 15 | 11 | 8 | 35 | 24 |
| Positive | 0 | 4 | 0 | 37 | 8 | 13 | 12 | 50 |

*A = without satisfactory evidence from physical examination or from patient's history of a previous syphilitic infection.

B = with some reasonable evidence of a previous syphilitic infection, either from physical examination or from history.

The results were tabulated from the material in the tables being referred to. In each table, the "A" and "probable" cases are given in the first column of the glandular test, the "B" and "positive" cases in the second column. In the glandular test, the "A" and "probable" cases are given in the first column of the glandular test, the "B" and "positive" cases in the second column. In the glandular test, the "A" and "probable" cases are given in the first column of the glandular test, the "B" and "positive" cases in the second column.

Control cases. In the control cases, the sign was not present. In the control cases, the sign was not present. In the control cases, the sign was not present.

Conclusion. The sign is a reliable indicator of old syphilis. The sign is a reliable indicator of old syphilis. The sign is a reliable indicator of old syphilis.

A DEMONSTRATION OF THE SPIROCHAETA PALLIDA OF SYPHILIS, WITH DESCRIPTION OF RAPID METHOD OF STAINING.

BY T. J. MANAHAN, M.D., BOSTON,
From Pathological Laboratory, Massachusetts General Hospital.

In May, 1905, Schaudinn and Hoffman presented their work on the occurrence of a spiral-shaped organism in syphilitic lesions. This organism they named the *Spirochaeta pallida*. Their observations were confirmed by Metschnikoff one month later. Since then a great many confirmatory observations have been made by others in this country and abroad. The evidence is conclusive that primary lesions, condyloma, macular, papular, pustular lesions and mucous patches contain the *Spirochaeta pallida* either constantly or in the majority of cases. Schaudinn has demonstrated it in aspirated splenic juice taken from a case of recently acquired syphilis. Rickzet and Noeggerath have found it in the blood, while several others have failed. The pallida has been found in the skin of congenital syphilitic children. A most interesting case was one of Flexner's, who found the organism in skin lesion of a child whose mother acquired syphilis five years before. Metschnikoff and Flexner have found the *Spirochaeta pallida* in monkeys which have been successfully inoculated with syphilis.

The *Spirochaeta pallida* measures 4 to 10 microns long and $\frac{1}{2}$ micron wide. The curves are short, corkscrew-like, and vary in number from 4 to 20. The organism is motile, rotating on its long axis, and has sharpened ends. Flagella have been observed. I have observed a forking at the end in one specimen. Other spirilla occur about the healthy genitals and in non-specific ulcerations. The form seen most frequently is the *Spirochaeta refringens*. This organism is broader, has longer and fewer curves and stains more intensely than the pallida. There is no difficulty in differentiating them after one has made many observations. In a recent paper, Schaudinn and Hoffman state that it is their conviction that the pallida is the definite cause of syphilis. Metschnikoff expresses confidence and thinks syphilis is a chronic spirilla infection.

The first specimens I examined were stained by the Geimsa method, which is the one first recommended by Schaudinn and Hoffman. This method requires eighteen hours and stains the *Spirochaeta pallida* very faintly. On experimenting with Dr. Wright's blood stain I found the organism could be much more intensely stained in a period of five minutes with this stain. This rapid and more intense method of staining is a great advance, as it saves time and makes the recognition of the organism comparatively easy. The application of Wright's blood stain to the staining of smears obtained from syphilitic lesions is as follows: The stain is prepared according to the directions given in Mallory and Wright's "Pathological Technique," page 371.

Five tenths of a gram of the dried methylene blue eosin precipitate is added to 100 cc. of pure

methyl alcohol, Merck's guaranteed reagent, and after a concentrated solution is obtained, the solution is filtered. Take 30 cc. of the filtrate and add 10 cc. of pure methyl alcohol.

This solution is now ready for use and should be kept in a tightly corked bottle to prevent evaporation. If evaporation takes place, a precipitate will form which will so obscure the specimen as to prevent the recognition of the organism.

The film is covered drop by drop with as much of the staining fluid as the coverglass can conveniently hold and allowed to remain one minute. Water is then added, drop by drop, until a metallic film appears on the surface. In my experience I have found that four drops give the best results. The stain is now kept on for five minutes and then washed in water. The amount of water used should be just enough to remove the staining fluid. On examination, the red corpuscles should be a pale blue and the *Spirochaeta pallida* purple. If the differentiation is carried any further with water, the spirochaeta do not stain as deeply. The coverglass is dried over the flame and mounted in balsam. Preparations should be made with great care, in order to prepare thin and evenly distributed smears. The method of obtaining the material depends on the seat and character of the lesions.

In chancres, where ulceration has taken place, the following method has been found most suitable: The lesion is washed with water and gauze, removing as much of the necrotic tissue as possible. At the junction of the ulcerated area with the indurated margin a small incision, 4 mm. long and 2 mm. deep, is made with a tenotome. The first few drops of blood are removed with gauze and the bleeding checked by pressure. Then with the back edge of the tenotome a small amount of material from the bottom and sides of the wound is removed. This material, which will be blood-tinged serum, is then placed on a $\frac{3}{4}$ -inch coverglass, which has been carefully washed in absolute alcohol and ether and a smear made in the same manner as you would prepare a blood smear. In mucus patches two methods are employed to obtain the material. The selection of the method to be used depends upon the character of the lesion. In fissures of the tongue or mucus patches which have gone on to ulceration, the lesion is washed with gauze and water. The necrotic material is then removed with a small, blunt curette. After the bleeding has stopped, the base of the fissure or ulcer is gently scraped with the curette. The material thus obtained is placed on a coverglass and a smear made. In early mucus patches before ulceration takes place, the procedure is as follows: The edge of the diseased mucous membrane is lifted with a tenotome and from the wound a drop or two of the blood-tinged serum is placed on a coverglass and a smear is made.

Preparations from the skin eruptions may be made by one of the two following methods:

A bleb is made by the application of strong ammonia over the skin lesion. When the bleb is formed, remove the serum with a platinum

loop and make a smear. This method has not been satisfactory. Another and more satisfactory way is to scrub the skin thoroughly with alcohol and water. Then select a well-developed macule or papule and scrape off the upper layers of skin with a knife until a bloody serum exudes. A good-sized drop of bloody serum is allowed to form. Remove this drop by touching it with the surface of a coverglass. The drop will adhere to the coverglass and a smear is then made.

later characteristic eruption appeared. The diagnosis of syphilis was made and the patient placed under treatment. The treatment has been constant and the only lesions now are two mucous patches. Smears from the mucous patches showed many spirochaeta pallida.

CASE VII. Male; age, twenty-one. Two months ago developed gonorrhea and an ulcer on the penis. One month ago throat and mouth became sore and at this time he noticed a faint skin eruption. At present he has several mucous patches and anal condylomata. Clinical diagnosis syphilis. Smears from mucous

smears positive. Several smears were examined in two lots. The second smears were taken four days after the first examination. Later the patient developed a phymosis and was circumcised. Following the operation the local condition improved rapidly and was discharged well five weeks later with no evidence of syphilis. (See plate.)

CASE VI. Male, age, twenty-eight. Had gonorrhea for three months. Ten days ago a sore came on penis following coitus three weeks previous. Six weeks

later characteristic eruption appeared on forearm and palms. Remains of induration on prepuce. Enlarged epitrochlear glands. Tonsils enlarged. Several decaying mucous patches. Clinical diagnosis, syphilis. Smears taken from mucous patches show many spirochaeta pallida.

CASE VIII. Male, age, twenty-four. He had a sore on the upper middle surface of penis 14 mm. in diameter, slightly indurated. The center is covered with no rotting granulation tissue, the edge is clean cut,

A DEMONSTRATION OF THE SPIROCHAETA PALLIDA
OF SYPHILIS, WITH DESCRIPTION OF RAPID
METHOD OF STAINING.

BY T. J. MANAHAN, M.D., BOSTON,
From Pathological Laboratory, Massachusetts General Hospital.

IN May, 1905, Schaudinn and Hoffman presented their work on the occurrence of a spiral-shaped organism in syphilitic lesions. This organism they named the *Spirochaeta pallida*. Their observations were confirmed by Metschnikoff one month later. Since then a great many

methyl alcohol, Merck's guaranteed reagent, and after a concentrated solution is obtained, the solution is filtered. Take 30 cc. of the filtrate and add 10 cc. of pure methyl alcohol.

This solution is now ready for use and should be kept in a tightly corked bottle to prevent evaporation. If evaporation takes place, a precipitate will form which will so obscure the specimen as to prevent the recognition of the organism.

The film is covered drop by drop with as much of the staining fluid as the coverglass can con-

makes the recognition of the organism comparatively easy. The application of Wright's blood stain to the staining of smears obtained from syphilitic lesions is as follows: The stain is prepared according to the directions given in Mallory and Wright's "Pathological Technique," page 371.

Five tenths of a gram of the dried methylene blue eosin precipitate is added to 100 cc. of pure

of the diseased mucous membrane is fixed with a tenotome and from the wound a drop or two of the blood-tinged serum is placed on a coverglass and a smear is made.

Preparations from the skin eruptions may be made by one of the two following methods:

A bleb is made by the application of strong ammonia over the skin lesion. When the bleb is formed, remove the serum with a platinum

loop and make a smear. This method has not been satisfactory. Another and more satisfactory way is to scrub the skin thoroughly with alcohol and water. Then select a well-developed macule or papule and scrape off the upper layers of skin with a knife until a bloody serum exudes. A good-sized drop of bloody serum is allowed to form. Remove this drop by touching it with the surface of a coverglass. The drop will adhere to the coverglass and a smear is then made.

Through the kindness of Drs. J. T. Bowen, C. J. White, D. F. Jones and H. Cabot, I was able to obtain material from eighteen cases. These cases were from the Skin, Surgical and Genito-Urinary Out-Patient Departments of the Massachusetts General Hospital.

CASE I. Male; age, thirty-two. Ulcer appeared on penis three weeks after coitus. At present time, five weeks from appearance of sore, there is an ulcer on the corona 1 cm. in diameter with indurated edges. There is a macular papular eruption on the chest, back, abdomen and arms and also a mucous patch on the lower anterior gum. (See plate.)

The clinical diagnosis was syphilis.

Coverglasses were taken from the ulcer and showed several spirochaeta pallida. The examination of the mucous patch showed many spirochaeta pallida, there being about three times as many as seen in the smear from the penis. The smears from the skin and blood were negative.

CASE II. Male; age, seventeen years. Gonorrhea for two weeks. Twenty-three days after coitus a small sore appeared on the penis. Four weeks later a fine papular eruption on the chest, back and arms. The diagnosis of syphilis was made at this time. Eleven weeks later I examined smears taken from the skin. At this time the eruption was fading. I examined ten smears all of which were negative, likewise smears from the blood.

CASE III. Male; age, eighteen. Light weeks ago primary lesion on penis, followed five weeks later, by a macular eruption on body and arms and is still present. The clinical diagnosis of syphilis was made on the day the smears were examined, and the case up to this time had no anti-specific treatment. I made smears from a young papule and found a few spirochaeta pallida. The blood smears were negative.

CASE IV. Male; age, twenty-four. Three weeks ago sore came on penis two weeks after coitus. On the under side of the frenum is a hard ulcerated area. The epithelial, inguinal and post-occipital glands are enlarged and there is an eruption on the chest and arms. Clinical diagnosis syphilis. Smears from ulcer showed several spirochaeta pallida, while smears from the skin macule and the blood were negative.

CASE V. Male; age, twenty-six. Urethral discharge for two weeks. Examination shows urethral discharge with multiple indurated ulcers about the prepuce. Inguinal glands enlarged but not tender. Smears made from the ulcers failed to show any of the spirochaeta pallida. Many smears were examined in two lots. The second smears were taken four days after the first examination. Later the patient developed a phimosis and was circumcised. Following the operation the local condition improved rapidly and was discharged with five weeks later with no evidence of syphilis. (See plate.)

CASE VI. Male; age, twenty-eight. Has had gonorrhea for three months. Ten days ago a sore came on penis following coitus three weeks previous. Six weeks

later characteristic eruption appeared. The diagnosis of syphilis was made and the patient placed under treatment. The treatment has been constant and the only lesions now are two mucous patches. Smears from the mucous patches showed many spirochaeta pallida.

CASE VII. Male; age, twenty-one. Two months ago developed gonorrhea and an ulcer on the penis. One month ago throat and mouth became sore and at this time he noticed a faint skin eruption. At present he has several mucous patches and anal condylomata. Clinical diagnosis syphilis. Smears from mucous patches showed many spirochaeta pallida.

CASE VIII. Male; infant, three months old. Two weeks ago skin eruption appeared. The child is thin, anemic and poorly nourished. Examination shows a general macular eruption on body with papular eruption on palms and soles of feet. Abdomen enlarged. Clinical diagnosis, congenital syphilis. Examination of smears from skin lesions were negative. In this case I examined twenty slides taken from arms, body and legs.

CASE IX. Female; age, twenty. Ten days ago a small sore appeared on the middle of the lower lip. Since then it has increased in size and is now 8 mm. in diameter. It is an indurated, somewhat elevated ulcer. Under the angle of the left jaw is a hard, tender swelling the size of a large marble. Clinical diagnosis, ulcer of lip with septic gland. Smears were taken from the ulcer and were negative, although many slides were examined. One week later a second examination was negative.

CASE X. Female; age, twenty-three. Fourteen months ago was treated in the Out-Patient Department for multiple chancrels. Examination at that time showed the bacillus of Dancery. Five days ago she came again to the hospital with an ulcer on the upper lip which is in the median line, covered with a scab with a fissure in the center. Examination showed the post-occipital glands enlarged on each side. The pharynx is red and there are patches on the anterior pillars. Three weeks ago had a sore on the finger which has since healed. Complaints of severe headaches, general pains. She has been married one year, and two months ago gave birth to a child which is now said to be dying from consumption. Thus far I have been unable to obtain the child for observation and material. Clinical diagnosis, syphilis.

Examination of smears from the lip showed many spirochaeta pallida. (See plate.)

In this case the diagnosis was doubtful clinically. The value of a quick method of staining the spirochaeta pallida was well demonstrated in this case as a diagnostic measure.

CASE XI. Female; age, forty-two. Has been under treatment for syphilis for the past year. At times she has neglected carrying out the treatment. Fifteen months ago a gummatous nodule appeared on the upper anterior surface of the tongue. At the present time it is still present as an elevated hard area about the size of a quarter. Clinical diagnosis, gumma of tongue. Microscopic examination of smears from the surface and center of the gumma failed to show any spirochaeta pallida.

CASE XII. Male; age, twenty-three. Sore throat for three weeks. Macular papular eruption on forearm and palm. Remained indurated on prepuce. Enlarged epitrochlear glands. Tender enlarged. Several large inguinal mucous patches. Clinical diagnosis, syphilis. Smears taken from mucous patches show many spirochaeta pallida.

CASE XIII. Male; age, twenty-four. Has had a sore on the upper medial surface of penis 14 mm. in diameter, slightly indurated. The center is covered with necrotic granulation tissue, the edges clean cut,

There is an eruption on the body suggesting scabies. Clinical diagnosis, scabies, and diagnosis of ulcer deferred. Several smears were examined for the spirochaeta pallida, but all were negative.

CASE XIV. Female; age, twenty-three. Three months ago red pimples appeared on a portion of the interior aspect lower part of right leg. They enlarged in size and ulcerated and were followed by others of the same description. Otherwise well. Gives no venereal history. Clinical diagnosis, ulcers of leg. Smears were taken from the ulcers and showed many bacteria, but no spirochaeta pallida.

CASE XV. Male; age, twenty-five. Ten months ago sore on penis six weeks after last coitus, disappeared with cauterization. No rash. Three months ago three small sores on scrotum. Five days ago shifting pains followed by a lumpy petechial eruption, more or less over the entire body. Gums and tongue swollen. Physical examination: Glands in neck and groin. Penis gangrenous. Line of demarcation formed 8 cm. from pubes. The clinical diagnosis in this case is doubtful. The patient had a severe general infection but is now recovering under anti-specific treatment. Smears from granulating wound of penis were negative.

CASE XVI. Male; age, twenty. Has had trouble with penis for two weeks. Typical induration. Area on prepuce with porky roll. No ulceration. No other objective symptom. The patient does not speak English and it was not possible to obtain an accurate history. Clinical diagnosis, syphilis (?) Several smears were taken from sclerosed area and no spirochaeta were found.

CASE XVII. Male; age, twenty-eight. Sore on penis seven weeks ago coming on three weeks after coitus. At present time an indurated area on under side of corona with a granulating patch in the center. There is a generalized macular eruption over chest and back. The inguinal, post-occipital and epitrochlear glands are enlarged. There are mucous patches in the mouth. Clinical diagnosis, syphilis. Microscopic examination of smears shows several spirochaeta pallida in ulcer of penis and many more in the mucous patches.

CASE XVIII. Female; age, twenty-three. Has large swelling on upper lip which started four months ago like a cold sore. Picked it with a pin and it began to swell. Has not been painful. It is not as large now as it was three months ago and has been decreasing in size daily. The under surface of the tongue is furrowed and has patches. The lesion on the lip is 1.5 cm. in diameter, hard and is covered by thin mucous membrane. Vaginal examination: Hymen intact. Condylomata on vulva. Clinical diagnosis, syphilis. Primary lesion of lip. Smears from lip and tongue lesions show many spirochetes pallida.

Summarizing the observations made in these cases, I found the presence or absence of the *Spirochaeta pallida* to be as follows:

| | | SPIROCHAETA PALLIDA. | |
|---|------------------|----------------------|---------|
| | | Present. | Absent. |
| Clinical Diagnosis— Syphilis | Chancres, | 4 cases | 1 case |
| | Mucous patches, | 6 " | 0 cases |
| | Skin lesions, | 2 " | 3 " |
| | Blood, | 0 " | 4 " |
| | Gumma of tongue, | 0 " | 1 case |
| Clinical Diagnosis, Lesion of Non- Syphilitic Origin or Doubtful | | 0 cases | 6 case |

It is evident from these facts that the *Spirochaeta pallida* was present in the first group of cases constantly in the chancres and mucous

patches. In these cases the clinical diagnosis of syphilis was clear. In the chancre where I failed to find the organism the sore had completely healed. The failure to find them in the blood in view of the observations of others, is undoubtedly due to faulty technique on my part. In the six cases of the second group the clinical diagnoses were doubtful or other than syphilis. In these cases careful searching failed to show the *Spirochaeta pallida*, although the *Spirochaeta refringens* was frequently seen.

Conclusion. — From my observations I believe that the constant occurrence of the *Spirochaeta pallida* in typical syphilitic lesions indicates, first, that it is the organism which causes syphilis.

Second, that by method of staining which I have described in ulcers of the penis, an early diagnosis can be made without waiting for the appearance of secondary symptoms. This is a great advantage, because the treatment can be commenced before a general systemic infection has taken place.

Third, that the presence of large numbers of *Spirochaeta pallida* (in one case fifteen in one field) in mucous patches bears out well the known clinical fact as to the infectiousness of mucous patches.

DESCRIPTION OF PLATES.

The first and third microphotographs shown in the accompanying plates show two *Spirochaeta pallida*, one from a chancre and the other from a mucous patch where syphilis was acquired over one year before.

The second plate shows the *Spirochaeta refringens*. The excursion of the curves are longer and fewer in number than in the pallida. It can also be seen that the diameter of the refringens is slightly greater.

A CASE OF CONGENITAL OCCLUSION OF THE SMALL INTESTINE. OPERATION. AUTOPSY.

BY LINCOLN DAVIS, M.D.,

Instructor in Anatomy, Harvard Medical School; Out-Patient Surgeon, Massachusetts General Hospital;

AND

OSCAR RICHARDSON, M.D.,
Assistant Pathologist, Massachusetts General Hospital.

ON account of its comparative rarity and the problems involved in its pathogenesis, this case seems worthy of record.

Clinical History. — On Dec. 11, 1905, about 6 P.M., an infant twenty-six hours old, with a history of having passed nothing by rectum since birth, and of having vomited dark greenish material quite constantly during the last few hours, was seen in the accident ward of the Massachusetts General Hospital.

The baby had been sent to the hospital by Dr. D. J. O'Shea, of East Boston, with the diagnosis of intestinal obstruction. It was afterwards learned from Dr. O'Shea that the birth was in every way normal. The parents were well and strong. No history of tuberculosis or specific disease. There had been five other children in the family, one of whom died in infancy of marasmus, the others are living and well. This baby was born at full term at 4 P.M., on Dec. 10, and nothing was noticed to be wrong with him until the next morning, when there had been no movement of the bowels, and vomiting began.

Examination at the hospital showed a well-developed male infant without external malformation. The heart action was quite rapid. The abdomen was greatly distended and tense, presenting two distinct transverse bulgings and a sulcus between, across which peristaltic waves periodically passed. The abdomen was generally tympanic. Nothing in the way of a tumor was to be felt. A soft catheter was passed without difficulty into the rectum for a distance of three inches; repeated injections of warm water failed, however, to bring away any fecal matter.

The history of complete obstipation, the vomiting of matter resembling meconium, together with the signs of abdominal distention and visible peristalsis, made the diagnosis of intestinal obstruction seem certain. The nature of the obstruction, however, was not conjectured.

Operation.—An operation was decided upon and, under ether, an incision to the right of the median line made through the abdominal wall. Upon opening the peritoneal cavity, greatly distended small intestine popped out, an adhesion partially constricting a coil of distended intestine was freed; the gut which was much distended beyond this point, was followed down and found to end in a free blind sac. Continuing the exploration a mass was felt in the right flank adherent to the lower edge of the liver. When this was lifted up into view, it was seen to be composed of fine coils of undeveloped intestine held together by adhesions, and resembled closely a mass of earth worms. This mass was dropped back, and the greatly distended upper segment of intestine was tapped with a trocar, with the evacuation of a considerable amount of gas and semi-fluid greenish material. The blind end of the intestine was then sutured into the wound and the opening in the gut enlarged.

The baby stood the operation fairly well. There was very little fecal discharge from the artificial anus, but some oozing of blood. Attempts to give salt solutions by rectum were unsuccessful; after one rectal injection a stringy white cast was passed. There was occasional vomiting. The baby gradually failed and died twenty-four hours after the operation.

Autopsy.—Permission was obtained for a post-mortem examination and the following conditions were found to be present:

The body is that of a male infant, forty-eight hours of age, 45.5 cm. long, well-developed, fairly nourished. Head. Not examined.

Trunk: The thoracic viscera and cavities on section are normal.

On the right side of the abdominal wall there is a linear wound 5.5 cm. in length closed with sutures.

The peritoneal cavity is free from fluid. The serosa of the intestines near the wound of operation is blackish red in color and shows here and there a slight amount of grayish soft exudate. In one or two places the coils of the small intestine are slightly glued together by grayish soft exudate. In what is apparently a free blind end of the small intestine there is a surgically opening. The base of the umbilicus is normal.

The liver, stomach, pancreas, spleen, kidneys and adrenals on section are normal in appearance and have the normal anatomical relations. The duodenum is distended, but otherwise is normal in appearance. Bile flows from the duodenal papilla on pressure of the gall bladder. The gall bladder is normal in appearance and free from stones. The duodenum measures in circumference 4 cm. and is continued as the jejunum with normal anatomical relations. Of this portion of

the small intestine there is present, however, only a distended portion of the tube measuring about 46 cm. in length, and varying in circumference from 4.5 cm. to 7 cm. The mucosa shows strikingly well-marked rugae more prominent towards the distal end of the tube. The contents of this part of the intestine consists of a soft dark greenish-brown material. The portion of the jejunum present ends blindly and shows in its free blind end the surgical opening previously referred to. It is supported by a crescentic flap of mesentery which averages about 2 cm. in width and which springs from the usual situation of the root of the mesentery. The margin of the mesentery away from the intestine is free, smooth and rounded and in several places in it small lymphatic gland-like bodies are visible.

The rectum, sigmoid flexure, descending colon, splenic flexure, transverse colon and hepatic flexure have their normal anatomical relations and on section show no lesions of the mucosa. The large intestine contains a considerable amount of pale, gelatinous, mucous-like material and measures in circumference from 1.5 cm. to 2 cm. In the situation of the hepatic flexure the colon turns down and reaches to a point at the level of the lower pole of the right kidney at which point there is a small pouch-like dilatation. From this portion of the colon a smaller tube continues, extending upward and over across the ascending colon where, just to the right of this and a little above the distended pouch-like portion of the colon, it is lost in what is apparently a complicated coil of intestine. This knot-like mass of intestine, which measures 2 cm. by 1.5 cm. by 1 cm. is bound by fibrous tendon-like adhesions to the inferior surface and lower margin of the right lobe of the liver and to the peritoneum over the perinephric tissues in the region of the lower pole of the right kidney anteriorly. Where the small portion of intestine continues from and over the ascending colon there is a short prolongation along it of the mesentery from its root. On unravelling the complicated coil of intestine it is found to be made up of a length of the lower end of the ileum about 45 cm. long. This portion of the small intestine ends blindly in the coil and the other end joins the pouch-like portion of the ascending colon, which is in the situation of the cecum, with the same anatomical relations that it has in the adult. On section the ileocecal valve has its normal relations. Springing from the base of the pouch-like portion of the ascending colon or cecum there is an appendix-like organ the distal half of which is bound by fibrous-like tissue along and to the ileum. This appendix-like tube measures about 1 cm. in length and averages about 3 mm. in diameter. Water passes through the large intestine until it reaches the cecum where it passes into and distends the appendix. The water also passes into the small intestine over a length of about 1 cm. above the ileocecal valve. Here the small intestine is constricted and occluded by fibrous-like tissue. From this point on the portion of ileum present is more or less constricted at irregular intervals by fibrous-like connective tissue which broadens out in places into a membranous-like band which is inserted all along the wall of the ileum similar to the insertion of the mesentery in the wall of the ileum in the adult. The ileum is quite small, being about 4 mm. in diameter in its largest portion. About 5 cm. above the ileocecal valve there is a small mass of tissue which measures 1 cm. by 5 mm. by 3 mm. and is attached to the wall of the ileum by fibrous tissue. The mass is possibly gland tissue or a small piece of the ileum separated in uncoiling the knot of intestine. A piece is put away for microscopic examination. On section of the small intestine where possible, no lesion is

are made out, but there is in portions of its lumen a slight amount of yellowish, soft, mushy material.

There is no good evidence of the presence of a Meckel's diverticulum anywhere along the course of the small intestine.

The ureters, bladder, prostate and testes are normal in appearance and have their usual anatomical relations.

Microscopical examination of one of the mesenteric lymphatic glands and of the small mass of tissue attached to the ileum shows nothing remarkable. The mass is regarded as being a small portion of the ileum separated off in untangling the coil of intestine.

From the above findings the case is clearly one of congenital malformation of the small intestine with complete interruption in the continuity of the intestinal tube and consequent intestinal obstruction.

Occurrence. — A somewhat limited review of the literature of this subject reveals quite a collection of recorded cases of congenital abnormalities of the upper intestinal tract. These abnormalities vary in degree from stenosis and stricture to complete obliteration and severance of the alimentary canal. In some cases the blind ends of the gut are connected by an impervious fibrous cord; more rarely, as in our case, there is no connection between the two ends. A few cases have been reported where a segment of the bowel has been actually missing. These malformations are often multiple and in some cases are accompanied by other congenital defects, such as umbilical or inguinal hernia, atresia of the anus, hypospadias, etc.

The most common site for congenital intestinal atresia, excluding, of course, the rectum and anus, is in the vicinity of the ileum or at least within the primitive intestinal loop, and next in frequency in the duodenum. The form of defect illustrated by this case, that is, complete severance of the canal without connection of the blind ends, although reported in a few instances in the duodenum, is much commoner in the lower jejunum and ileum.

Gaertner, in 1883, collected 64 cases of stenosis or atresia of the small intestine. There were 27 in which the intestine had a blind ending, though in some of these the ends of the gut were connected by an impervious cord. Of these 27, 9 were in the duodenum, and 16 in that portion of the intestine corresponding to the primitive loop.

Since then quite a number of additional cases have been reported by various observers, and cases identical to ours have been reported by Lillienfeld and Archambault.

Braun, in 1902, collected 25 cases of congenital occlusion of the ileum or jejunum which were operated upon, all with fatal results. In one case there was survival for fifteen days after the operation. There have been a few operated cases reported since then with a like result.

Pathogenesis. — As to the cause of congenital occlusion of the upper intestinal tract, many theories have been advanced and some striking cases cited in their support. Probably no one theory can explain all the cases.

The most prominent theories are that these defects are due to the results (1) of fetal peri-

tonitis; (2) of volvulus; (3) of compression or snaring of a portion of the gut by the closure of the cavity of the umbilical cord.

The latter theory was first elaborated by Ahlfeld, in 1873, who ascribed such defects to an abnormal persistence of the vitelline duct, whereby the loop of intestine which in the course of development enters the cavity of the umbilical cord, is prevented from returning to the abdominal cavity at the proper time, which results in its being pinched or snared off, as the case may be, by the closure of the abdominal walls. This theory accounts for those cases in which a segment of the intestine is entirely lacking. By an ingenious elaboration of the same theory, Ahlfeld includes atresia of the rectum and anus as secondary results of the undue persistence of the vitelline duct due to traction on the intestine. He records a case which seems to confirm his theory, and similar cases have been reported by others, notably by Clogg. This theory has, on the whole, been quite generally accepted.

That volvulus within the abdominal cavity during fetal life may result in atresia cannot be denied, and that this result may even take place in adult life under peculiar conditions seems to be shown by the remarkable case reported by Hädlich.

That other causes also may be productive of these defects seems to be shown by scattered reports of cases in which invagination of the intestine, disease of the mucosa, or the pressure of a tumor have been the causative factors.

The conditions found in the case here reported are most satisfactorily explained by a strangulation of a portion of the intestine, together with its mesentery, which resulted in a complete severance at one point, and an atrophy and non-development of that portion which had been partially deprived of its mesenteric blood supply. It is evident from the absence of bile-stained matter within the intestine below the site of occlusion, that the lesion occurred early in fetal life before the establishment of biliary secretion, that is, before the end of the third month. The remarkable changes in position of the primitive loop of intestine at about this same period in connection with its migration into the cavity of the umbilical cord, and its withdrawal therefrom, would seem to offer a most favorable opportunity for such strangulation. This seems to us the most plausible theory by which to explain the conditions found in this case. The adhesions and enlargement of the mesenteric glands may be fairly considered as the result of inflammatory reaction due to the strangulation.

Treatment. — As to the treatment of this well-nigh hopeless condition, the formation of an artificial anus seems the only solution. An intestinal anastomosis between the dilated portion alone, and the shrunken gut below the occlusion, offers insurmountable technical difficulties. Braun makes a very good suggestion in proposing to bring out both blind ends of the intestine through the wound; this would allow of forcible dilatation of the distal segment by means of

injections from above, and the performance of an intestinal suture outside the abdominal wall at a later date if occasion offered. A suggestion of J. W. Elliot for maintaining nutrition in cases

incision in the neck, on the right, and was freed from the bodies of the vertebrae. An exostosis as large as an orange seed was removed from the body of what seemed like the sixth or seventh cervical vertebra. Further on in the bodies of the vertebrae a tumor was

of the esophagus. A small probe, the size of a lead, which passed to the first part of the esophagus, was introduced into the esophagus with the esophagus to the left of the body of the esophagus. No attempt was made to pass the probe into the stomach and some distance into the stomach. The esophagus was exposed by a long, wooden probe to guide it from

are made out, but there is in portions of its lumen a slight amount of yellowish, soft, mushy material.

There is no good evidence of the presence of a Meckel's diverticulum anywhere along the course of the small intestine.

The ureters, bladder, and associated structures are in appearance and position normal.

Microscopical examination shows that the lymphatic glands attached to the ileum are separated off in units.

From the above it is evident that the congenital malformation is a complete interruption of the intestinal tube and consists of:

Occurrence.—A review of the literature of this subject shows that there are a number of recorded cases of congenital atresia of the upper intestinal tract, varying in degree from simple stenosis to complete obliteration and absence of the canal. In some cases the atresia is connected by a narrow band more rarely, as in the case reported here, by a complete interruption between the two segments. It is reported where a single atresia is actually missing. It is also reported multiple and in some cases associated with other congenital malformations, such as inguinal hernia, hydrocephalus, etc.

The most common form of congenital atresia, exclusive of the duodenum and anus, is in the ileum. The next in frequency is atresia of the jejunum. The defect illustrated in this case is a complete severance of the intestinal tube at the blind ends, a condition which has been reported in the duodenum and the lower jejunum.

Gaertner, in 1881, reported a case of atresia of the small intestine in which the intestine was found to be connected by an imperforate membrane. He was in the duodenum and the intestine connected by a band.

Since then quite a number of cases have been reported which are identical to the case of Lillienfeld and Braun.

Braun, in 1902, reported a case of complete occlusion of the small intestine which was operated upon, a case in which there was no connection between the two segments. There are several other cases reported since.

Pathogenesis.—Theories have been advanced to explain the occlusion of the small intestine.

Probably no one theory can explain all the cases. The most prominent theories are that these defects are due to the results (1) of fetal peri-

tonitis; (2) of volvulus; (3) of compression or snaring of a portion of the gut by the closure of the cavity of the umbilical cord.

The latter theory was first elaborated by Ahlfeld in 1872, who ascribed such defects to

Braun makes a very good suggestion in proposing to bring out both blind ends of the intestine through the wound; this would allow of forcible dilatation of the distal segment by means of

injections from above, and the performance of an intestinal suture outside the abdominal wall at a later date if occasion offered. A suggestion of J. W. Elliot for maintaining nutrition in cases of fistula high up in the intestinal tract by catching the intestinal contents from the afferent segment and injecting them into the efferent, would seem particularly applicable to such cases.

BY F. B. HARRINGTON, M.D.

CASE I. B. H., male. Three months before entering the hospital, this man, thirty years of age, had a severe attack of nausea and vomiting with distention of the abdomen lasting several days. Since then there have been signs of chronic obstruction of a mild degree until six days before entrance, when another attack of almost complete obstruction came on. When seen the patient was distended and tympanitic all over the abdomen.

No cause for the obstruction could be made out. Incision in the middle line below the umbilicus showed the small and large intestines distended as far as the hepatic flexure of the colon, where a mass as large as a lemon could be felt. This was evidently the point of obstruction.

A Muxter tube was inserted in the ileum about eight to ten inches from the cecum; the patient was at once relieved and rapidly improved.

A week later, after the distention had subsided, the colon at the hepatic flexure was resected, removing the tumor, and a large segmented ring used to unite the cut ends. The segments came away on the fifth day with a rectal movement. The median fecal fistula closed itself in a little over four weeks.

Pathological report. Malignant adenoma.

Resection and anastomosis of the large intestine should never be attempted in the presence of great distention.

CASE II. Miss C., age, forty years. For two and a half months patient had been unable to swallow solid food. When sent to the hospital by a small amount of liquid food could be swallowed. The new esophageal regurgitation. A solid mass could be felt in the pharynx attached to the bodies of the fourth, fifth, and sixth cervical vertebrae, diminishing the size of the pharynx, especially on the right side, and crowding the opening of the esophagus. A small probe, the size of a lead pencil, was introduced into the esophagus with difficulty. No attempt was made to pass the probe into the stomach. The esophagus was exposed by a long

incision in the neck, on the right, and was freed from the bodies of the vertebrae. An exostosis as large as an orange seed was removed from the body of what seemed like the sixth or seventh cervical vertebra. Higher up on the bodies of the vertebrae a tumor was felt, which proved to be an osteo-arthritis deposit, and which caused the pharyngeal tumor. A probing was inserted into the esophagus to a point about one and a half inches above the sternum when it could be moved no farther. It was then possible with the finger in the incision to detect a tumor in the esophagus at this point. An incision was made on the left and the esophagus separated from the trachea and the bodies of the vertebrae as low down as the sternal notch. The tumor was excised with about one and a half inches of the esophagus, the opening on two sides rendering manipulation easy.

Pathological report.— "A new growth involving the whole of the esophagus about 3 cm. in length causing almost complete constriction and measuring about 1 cm. in greatest thickness.

"Microscopic examination showed solid masses of flat epithelial cells infiltrating the tissue in all directions. In many of these masses there were indurated horny whorls.

"Diagnosis: Epithelioma."

The esophageal end, opening into the pharynx, was closed by a purse-string suture of chronic gut. It closed the pharynx from the wound and there was never any leakage. The lower end of the esophagus was attached to a flap of the skin through half of its circumference. A rubber tube was inserted well into the esophagus through which the patient was fed. Convalescence uneventful. The patient has gained ten to twelve pounds. She feeds herself through the tube with little difficulty.

CASE III. W. H. L., fifty years old, male. In October an attempt was made to clean up a shagging tumor of the axilla which involved the vessels and nerves. This operation was followed by partial relief, but the farther development of the disease caused great swelling of the hand and forearm and great distress from pressure on the nerves. The only procedure which offered any relief from pain was complete removal of the arm with the shoulder blade and collar bone. The clavicle was disarticulated and the blood supply of the shoulder was cut off at the thyroid axis. The thyroid axis consisted of but two vessels, the inferior thyroid and the transverse costal arteries, the supra-scapular artery arising directly from the subclavian artery. These were tied and the subclavian was tied in its third part. The brachial plexus was injected with a cocaine solution before amputating. There was no shock. Whether this was due to the absence of loss of blood or to the use of the cocaine, I am not certain. I believe that the freedom from blood loss was the result of cocaine.

The patient, as a reward, has made an excellent recovery. The shoulder directly involved the artery costal axis, so that it had to be removed. The new attachment of the axilla was made by a graft from the latissimus muscle.

Microscopic examination showed a growth of a slightly elongated epithelial cells with a tendency to extreme anastomosis.

"Diagnosis: Carcinoma."

CASE IV. S. D., age, forty-two, male. W. H. L. who had been a week past eating solid food, was brought to the hospital with a tumor of the neck, the size of a lead pencil, which was found to be a carcinoma. The tumor was removed, and the esophagus was exposed by a long incision in the neck, on the right, and was freed from the bodies of the vertebrae. An exostosis as large as an orange seed was removed from the body of what seemed like the sixth or seventh cervical vertebra. Higher up on the bodies of the vertebrae a tumor was felt, which proved to be an osteo-arthritis deposit, and which caused the pharyngeal tumor. A probing was inserted into the esophagus to a point about one and a half inches above the sternum when it could be moved no farther. It was then possible with the finger in the incision to detect a tumor in the esophagus at this point. An incision was made on the left and the esophagus separated from the trachea and the bodies of the vertebrae as low down as the sternal notch. The tumor was excised with about one and a half inches of the esophagus, the opening on two sides rendering manipulation easy.

longed outing, he felt much discomfort in the epigastrium and noticed a slight swelling in the middle line above the umbilicus. When seen, six weeks after the accident, there was no tenderness over the swelling and no fever. The patient was referred to me by Dr. Shattuck for operation. The tumor gave a sense of fluctuation and its location suggested connection with the pancreas. An incision through the abdominal wall disclosed the gastro-colic omentum stretched over a fluctuating tumor as large as a large orange. The lesser sac was opened through the gastro-colic omentum. The tumor was tapped and 8 oz. of a slightly turbid, light amber fluid were removed. This fluid was found to be inert, but a subsequent discharge, which was quite active for a time, caused marked excoriation of the skin and was found to change starch into sugar. The edges of the cyst were sewed to the parietal peritoneum and drainage tubes inserted. The discharge of the fluid ceased within a short time. The patient was discharged in three weeks with a small granulating wound.

A CASE OF HYPERNEPHROMA.

BY F. C. SHATTUCK, M.D.

THE following history of a patient in my wards in whom the diagnosis of hypernephroma was made and confirmed by operation, is not without interest.

The patient, a man of thirty-nine, a cook, whose family history, previous history and habits have no bearing upon the case, entered the Massachusetts General Hospital in December, 1905.

Eight months ago, in May, while preparing for bed, he noticed that the right side of his abdomen felt hard; there had, up to this time, been no impairment in health, nor was there until August, four months later. At this time he began to have a dragging pain in the right side of the abdomen, not constant, not keeping him awake at night, but on account of the increasing size of his abdomen he had to let out the waist band of his trousers. His work began to bother him and he lost his ambition. His condition remained as above described, except for the steadily increasing size of the mass in the right side of the abdomen, until ten days before entrance to the hospital, when he was seized with a sharp, knife-like pain in the region of the tumor, the pain often shooting down the right leg. He had to stop work the pain was so severe. For five days the pain was almost constant, then gradually became less severe. During the past five months he has lost seventeen pounds in weight. There has been no hematuria.

At the time of entrance to the hospital, he was well developed, but somewhat emaciated. Temperature, 98.4; pulse, 100; respiration, 27. The examination of the heart and lungs was negative. There were a few palpable glands in the axillae and groins. Of especial interest was the examination of the abdomen. There was bulging in the right flank and the whole right side of the abdomen was dull upon percussion; there was also slight tenderness in this region. Extending from the right costal border to just above Poupart's ligament was a tumor mass, fairly smooth, irregular in outline. It extended to the median line above the umbilicus, while below it reached to four inches beyond. The tumor descended but slightly with inspiration, and the lower portion was traversed by the inflated colon.

Blood examination: Hemoglobin, 60%; red cells, 3,628,000; white cells, 6,400. Stained specimens showed nothing except a moderate secondary anemia.

Urine examination: Normal, acid; S. G., 1.018; slightest possible trace of albumin. The sediment

consists of a few red blood corpuscles and a few leucocytes; no casts seen. Cystoscopic examination, by Dr. Balch, showed a normal bladder wall, some enlarged veins about the right ureteral orifice; left ureteral orifice normal. Catheterization of ureters unsuccessful.

During his stay of two weeks in the hospital, the tumor increased considerably in size. He was seen in consultation by Dr. Harrington and operation advised. The right kidney was found to be replaced by the large tumor mass extending into the ureter and the entire growth was removed; the patient has made an uninterrupted convalescence. Pathological examination of the tumor showed it to be a perithelioma or hypernephroma.

OPERATION BY DR. F. B. HARRINGTON.

I was asked to see the case with Dr. Shattuck and agreed with him that an operation was desirable. I felt that the tumor was cystic, the sense of fluctuation being so perfect. In this I was in error, Dr. Shattuck being correct in his diagnosis. The greatest difficulty about the removal was to avoid tearing the renal artery and vein in the effort to tie off these vessels. The size and weight of the tumor was such that it was difficult to approach the vessels. On the removal of a flexible clamp I found the edge of the vena cava had been included in it, when the renal vein was clamped, there being distinct marks upon a portion of its circumference. This, however, caused no trouble, the patient making a rapid and steady convalescence. The ureter was removed with the tumor as low down as the brim of the pelvis. Its lumen for one half of its length was filled with a soft mass of disease.

Pathological report.—"The kidney was replaced by a lobulated mass of new growth, 25cm. in diameter on section, showing a yellow mass with a yellow opaque necrotic mass with the exception of the edge in places where there was a little medullary tissue. The pelvis was dilated and there was a tumor mass present in the ureter. Microscopic examination showed large, round cells separated by a stroma of connective tissue. Hypernephroma."

A CASE OF AMPUTATION AT THE SHOULDER JOINT FOR INFECTION WITH WELCH'S GAS-PRODUCING BACILLUS. RECOVERY.

BY E. A. CODMAN, M.D.

THE patient is an Italian. He was brought to the accident room in the night, seven weeks ago. Five hours before he had had his left arm caught in a revolving fan. He was seen by Dr. Plympton of Norwood, who partially cleaned up his wounds and sent him to the hospital. When he arrived his condition was so bad that Dr. Graves, the senior house officer, felt that any interference with the wounds which Dr. Plympton had partially sewed up would be fatal. There were compound fractures of the humerus and both bones of the forearm and numerous lacerated skin wounds. The wounds were irrigated superficially, splints applied and the patient left on the shock-table all night. During the next day he rallied, but it was decided to wait another day before attempting operation.

On the second day the crepitus of subcutaneous emphysema was noted over the whole arm and over the left side of the chest and neck. The forearm was obviously becoming gangrenous. He was seen by Dr. Harrington and the probability of infection with Welch's gas-producing bacillus considered. His general condition was very bad and a quick amputation was decided on. I amputated at the shoulder joint under light etherization and cocaineization of the brachial plexus. The wound was partially sutured and packed. The divided tissues were apparently healthy

except that they were distended with gas which escaped at times with a distinct sizzling noise as the knife passed along. A culture taken from the incision was negative.

For the following three days his condition was very critical, the emphysema persisting to a certain extent in the neck, chest and shoulder. On the third day I made an incision without any anesthetic about six inches long over the blade of the scapula at a point where the crepitus was greatest. I opened into a pocket of necrotic tissue and found the great muscles of the back distended by a very foul-smelling gas.

Although the patient had no ether I began pulling out of the wound great pieces of gangrenous muscle with occasional bits of scapula and ribs. I washed the wound out with carbolic 1-10 and packed it with gauze soaked in carbolic.

Since that time his condition has slowly improved and the wound will soon be ready for secondary suture.

Some idea of the condition of the arm and chest before amputation may be obtained from this photograph. The following is Dr. Richardson's report of the bacteriological examination of the amputated arm.

MASSACHUSETTS GENERAL HOSPITAL, CLINIC AND
PATHOLOGICAL LABORATORY.

Dec. 19, 1905.

BACTERIOLOGICAL EXAMINATION.—Shoulder tissues. Coverglass examination shows no bacteria and the cultures no growth.

The amputated arm was enormously swollen, necrotic, and the tissues yielded on section a large amount of foul fluid containing many gas bubbles.

Coverglass examination from the tissue of the upper part of the arm shows a few bacilli, morphologically like the *Bacillus aerogenes capsulatus*.

Coverglass examination of the tissues a little lower down shows great numbers of bacteria among which are bacilli like the *B. aerogenes capsulatus*.

Many cultures were made, but owing to the great numbers of other bacteria present, pure cultures were not obtained.

The glucose agar culture, however, showed the marked disintegration of the medium with forcing out of the tube plug due to the large amount of gas formed and which is characteristic of the presence of the *Bacillus aerogenes capsulatus* in this medium. Welch's test of inoculating a guinea pig by the introduction of the material into a vein and shortly after killing the animal and placing it in the thermostat over night was also done. The pig became enormously swollen, the skin being broken through in several places and the abdominal and thoracic viscera were disintegrated, necrotic and of the consistency of rotten sponge. The tissues yielded a foul fluid containing gas bubbles. This condition of the tissues is characteristic of the presence of the *Bacillus aerogenes capsulatus*.

Although a pure culture of the bacillus was not obtained it is considered from the above tests that the *Bacillus aerogenes capsulatus* was present in the tissues of the arm in association with great numbers of other bacteria and that the marked necrotic and emphysematous character of the lesion was due to its presence.

REMOVAL OF A CLASP PIN FROM THE RIGHT BRONCHUS AND A HAIRPIN FROM THE BLADDER

I want to show two foreign bodies which I removed about a month ago.

The first is a clasp pin which had been inhaled into the right bronchus of a girl nine months old. I removed this by Dr. Goodidge's method of introducing a urethroscope through a tracheotomy wound with the patient in Ross's position. With a head mirror it was easy to look through the urethroscope and see the pin in the bronchus and to grasp it with alligator forceps. It seems to me that Dr. Goodidge is greatly to be congratulated on discovering this simple method, and every surgeon ought to know about it.

The hairpin was removed from the bladder of a woman and was a much more difficult matter. The hairpin had been introduced by her husband, for what purpose we do not know. I first examined with a cystoscope and located the exact position of the pin. I could see that the points were sticking into the mucous membrane of the bladder in the left lateral orifice and that the axis of the pin pointed upward and to the right. After observing the exact plane of the pin I carefully removed the cystoscope and introduced a small lithotrite in the median line. I passed the lithotrite backward along the base of the bladder with its beak upward. I then lowered the jaws and rotated the beak to the left, as far as the base of the left lateral orifice where I knew the point of the pin was, and closed the jaws. I was fortunate enough to catch it by the tip, but not by the first time and to remove it with ease.

A. M. EASTMAN, HOPKINS CLINIC.

RECEIVED DEC. 20, 1905.

The patient, a girl, presented a large swelling at the upper end of the humerus. There was no pain or inflammation of the humerus. The swelling was

ances were those of sarcoma. Amputation of the upper extremity was performed. Microscopical examination discovered the growth to be a hypernephroma. Examination of the abdomen found a palpable and slightly movable left kidney. There had never been any signs or symptoms associated with the kidney in this case.

The case is instructive in that the bone metastasis was the first sign of the hypernephroma. In view of the fact that two cases of hypernephroma have been recorded in which solitary bone metastasis had taken place, the question arises. May not the bone metastasis in the case reported be solitary, and if so, is not a nephrectomy now permissible and advisable?

Reports of Societies.

AMERICAN ACADEMY OF MEDICINE.

The thirtieth annual meeting, held in Chicago, Nov. 9 and 10, 1905, with the President, DR. WINFIELD S. HALL, Chicago, in the chair.

REPORT OF THE COMMITTEE ON LAWS REGULATING THE PRACTICE OF MEDICINE.

This report was read by the Secretary, DR. CHARLES MCINTIRE, Easton, Penn.

The Academy began the study of laws relating to the practice of medicine in 1880, and the report gave some of the results of this twenty-five years' investigation. Some of the imperfections of the laws were considered. (1) The lack of uniformity in common with most legislation. In time this might be corrected. (2) The relation of vagarious practitioners. Each state by special legislation, by exemption in general legislation, or by sufferance, permitted certain classes of people to perform the office of a physician without the tests required by the state for doctors in medicine. The report suggested that the general practice acts should recognize this by providing for two classes. One to be known as "Limited Licentiates in Medicine," who would be examined only on the elementary subjects. As these laws were to protect the people, they should not take cognizance of any special system. Each one should have liberty to treat disease after his own sweet will, but only after he had demonstrated to the state officials that he possessed such knowledge of the human brain as the legislature had decided is necessary for the proper protection of the citizens. (3) Another imperfection of the laws of to-day was that they do not accept the statement of the medical college as final. This had been thought to have been necessary because some medical schools had been found not to have acted in good faith. The result was a somewhat mechanical statement of requirements. Time would right this, and the future laws would accept a diploma without going behind the returns. (4) Another weakness was the provisions for the transfer of a legal practitioner from one state to another. The report suggested that authority be given to each board to accept the license of another state at its value and to make such additional tests as might be required. (5) The laws too frequently failed to protect those who were licensed. They should provide for some official whose duty it was to search out and prosecute the unlicensed and those who were abusing their licenses. The report favored having osteopaths represented on State Medical Examining Boards.

DISCUSSION.

DR. CARL H. VON KLEIN, Chicago, referred to the gradual evolution that was taking place toward higher medical education, and said he had always been an earnest advocate of it. America was not behind in this progressive movement. In some medical schools the courses of instruction were equal to those established in foreign countries. There was a four-year course in Germany; a six-year course in Russia; an eight-year course in Italy, and all of these courses were different. In America the courses of instruction were almost equal to those in Austria and Germany; but the preliminary education of medical students had not reached as high a standard in this as it had in foreign countries.

DR. LEARTUS CONNOR, Detroit, Mich., called attention to the origin of medical laws, who originated them, and for what purpose. He said there were two parties involved: (1) The people, and (2) the doctors themselves. Doctors could not enact laws themselves, but they had to join with the people in accomplishing this. Doctors, however, had been the prime factors in establishing these laws, sometimes with a selfish purpose in view, he regretted to say. He thought that if doctors had looked disinterestedly after the interests of the people first, rather than their own interests, there would have been no need for any medical laws. While this was a strong statement, it was absolutely true. Physicians should work for the good of the community first, and for themselves secondarily. There should be a community of interest. With this idea in view, medical laws would be efficient, effective, in proportion to the support they received, and without such support they would be weak and ineffective.

DR. B. D. HARRISON, Sault Sainte Marie, Mich., said he could not agree with the recommendation in the report that osteopathy should be admitted as members of state medical examining boards, and be recognized as a part of the medical profession. Physicians could not afford to recognize a fake profession, such as osteopathy was, which was founded upon a fake condition, and was acknowledged to be such by its followers. It was simply suggestion. Three or four years ago he had occasion to inspect a school of osteopathy which held out inducements to graduates from all schools of medicine. He asked the dean many questions, and among them, "Who teaches anatomy in your school?" The dean replied, "Our professor of anatomy is a Rush College graduate." Again, he asked the dean, "Who are the assistant anatomists?" The reply was, "A Homeopath and an Eclectic." All anatomy, descriptive and applied, was taught in this school by these men.

He said that the Supreme Court of Kentucky held that the osteopath was a massmur. It was held by the Supreme Court of another state that osteopathy came within the field of medicine. Physicians had no right in principle to combine with osteopaths and accept them as members of examining boards, nor, in his judgment, had a board any right to have anything whatever to do with osteopaths or with any of the suggestive systems of practice — systems that were founded to "take in" the people. He referred to the Michigan law regarding osteopathy and osteopaths, and said it was only a matter of time when osteopaths would be driven out of that state. He favored letting them alone, as they would work out their own salvation or damnation.

He gave the following legal interpretation of qualifications numbers one and two in the report:

"If an applicant for the reciprocal indorsement of a certificate of medical registration or license had acquired such certificate or license in another state,

territory, district or province of the United States in medical reciprocity with Michigan, under conditions and requirements equivalent at the date of issue to those with which he would have had to comply subsequent to Sept. 22, 1883, in order to have then obtained the legal right to practice medicine and surgery in Michigan, such certificate or license may be recognized and indorsed by this board as a sufficient qualification for reciprocity under Section 3, subdivision third of Act 191 of the Public Acts of 1903, provided such applicant shall further comply with the rules and regulations of this board relative to the recognition and exchange of certificates or licenses between states."

Dr. R. O. BEYER, Minneapolis, Minn., believed that if the standard of the medical profession was raised there would not be need for medical legislation half so much as it was needed now. He was not at all sure but that at the present time, in view of the difficulties standing in the way of obtaining effective legislation for the control of the practice of medicine, the action of the state of Massachusetts was to be preferred to the action of the great majority of states in refusing to enact any law. It was a question of the "survival of the fittest," and he thought it would not be very long, after the medical profession had attained that standard of educational and professional fitness, before the bogus colleges would be relegated to the position of barbers, plumbers, etc.

The legislative side of the question was more difficult to deal with, as physicians were not as expert and successful in securing the enactment of laws as were others who were past-masters in politics.

Dr. JOHN M. DONSON, Chicago, said, urged by the medical profession, some schools had for several years established and arranged their work so as to prepare young men better for the study of medicine. Some institutions of general learning were now pursuing the plan of supplying courses in chemistry, physics, general biology, and others human anatomy, especially microscopic anatomy, bacteriology and embryology.

Prof. JAMES G. NEWMAN, Lake Forest University, Illinois, said it was to be regretted that the Minnesota State Board of Medical Examiners did not stand pat on educational qualifications rather than upon technicalities.

REPORT OF THE COMMITTEE TO TABULATE THE VALUE OF THE FIRST DEGREE.

This report was read by Dr. DONALD C. HAWLEY, Burlington, Vt.

The committee found it necessary to make a prefatory study before attempting the definite work assigned to it. This study included two questions:

(1) What is a college course intended to do? (2) What are the elements, which, when compounded, make the physician?

(1) A college was a factory where the value of the finished product depended upon the character of the raw material furnished. It also depended upon the process employed, but no process would cause a transmutation of metals. Unless the gold be in the ore, none could be found in the end products.

(2) To obtain material upon which to base the answer to this question, a circular letter was sent to a large number of physicians, medical teachers and others and college presidents. The replies received were studied by the committee, and were also included in the report as an appendix. The questions were:

(1) What is the character to be desired of the neophyte in medicine? To what extent can it be developed by educational processes? And what class of studies is adapted to bring it about?

(2) What mental discipline is essential that a student may profitably benefit by a medical course?

(3) What facts should be in possession of the intending medical student before he enters upon his medical studies? Can the acquisition of these facts be used to train the character and the mind?

The report discussed each of these topics in turn. It was admitted that sometimes the man with a limited training outstripped his fellow with greater scholastic advantage. There must be something underlying which educational processes could not supply. The boy or girl must belong to that type designated as "fact-seeker" by President Hadley, of Yale. He must also be self-reliant, able to arrive at fair conclusions on accurate observation, and to follow such conclusions with confidence. He must also have a bulldog tenacity, a love of seeking scientific facts apart from preconceived theories, and sympathy with mankind. These were foundations, and every trait which would make an honorable man and a cultured gentleman would be helpful.

Having boys and girls of this type, what should be the mental discipline to produce the best result? He should be taught to observe accurately and to interpret honestly the results of observation, to know how to study, to think logically, and train his memory to be of ready service. He should be educated first for the man, then for the physician. And, on the whole, the course in colleges leading to the A.B. degree seemed to be fitted for this better than any other course. Besides, the mind so furnished should be in possession of certain facts to be used directly in his medical studies. These included a knowledge of elementary physics, that he might understand its application in physiology and elsewhere; such a knowledge of chemistry as to make it necessary to teach only medical chemistry in a medical course; and general biology, that the student could undertake the study of life processes in man in an intelligent manner.

DISCUSSION.

Professor LEIST, Northwestern University, Chicago, emphasized that part of the report that students preparing for medicine should be advised to elect or to select studies in their college course, so that they might have two or three years of work in chemistry, biology, etc., and that they be advised to take up such subjects as histology, embryology, and comparative anatomy. Some institutions were pursuing such a course at present. He should like to see intending medical students advised to utilize their time, not so much with a further study of the classics, as with a liberal and long enough training to include general biology, comparative anatomy, histology and embryology.

Dr. FRANKLIN CONSON, Detroit, said a four-year course of study in medicine would have a much broader outlook, it would give him in a great measure, looking forward to what he ought to be, more to have a broad sympathy with the whole of those with whom he had to do. The science of the physician reached far beyond pathology, their therapeutic basis. The practice of medicine in a medical course, biology, have done so much to expand and to extend what started back in a body, whether he is a doctor or the best of friends of a doctor, that it is a pity that we have not more of a liberal education. A man can find out more about the world with the others with that background, that scientific character. If one, who had not a mind to be a physician, could stand in an operation, between two men, who had a slant on the book, who had a knowledge of the world. He was a holder of the "equivalent" of a medical degree, a doctor.

DR. CARL H. VON KLEIN, Chicago, pointed out and emphasized the value of an academic training preliminary to entering upon the study of medicine. The man who was academically well trained, other things being equal, made a good physician. A man should not be discouraged because he failed in his first examination, as there were notable instances of men who subsequently became great, yet who failed in their first examination. Among others he instanced Bismarck.

PROF. H. B. WARD, University of Nebraska, said that those who had not followed carefully the development of modern college education were not aware of the extent to which even in small colleges the elective system had been introduced. Formerly, a college course meant in the same section of country, or in a group of affiliated colleges, more or less the same training; not only four years, but four years applied relatively to certain lines, with some philosophy, some mathematics, some science, some literature and some history. The modern college had made a departure from this. Even the most conservative had introduced different courses which went under different names, but which in many, if not in all, cases led to the same degree, and in general he thought the degrees of B.S. and B.A. were apparently on a par with reference to future training. He not only emphasized but deplored the fact that there was not a series of recognized studies toward the professional line of medicine as there was in the mind of the college teacher with reference to theology, to law, or to some other vocation.

PROF. JAMES G. NEEDHAM, Lake Forest University, favored teaching general biology in colleges, letting the medical schools teach it as it applied to the human body. He would favor the colleges teaching general embryology, vertebrate embryology, but would let the medical schools teach those phases of it that applied to the human being and to the practice of medicine. The same with reference to other subjects. General colleges or universities could teach these branches to greater advantage than they were now being taught in medical schools.

DR. BURTON D. MEYERS, University of Indiana, said he had been studying seriously in connection with the medical department of the Indiana University the best means of developing and furnishing a preliminary education. The aim of those in authority was not to establish another medical school, but a medical department of the better kind, and they were ready to require four years of collegiate work if they were convinced that this was essential. A man who entered upon the practice of medicine ought to be able to use the English language correctly, to express himself clearly and concisely. He ought to be able to read French and German.

The report was further discussed by Drs. Daniel T. Nelson, John M. Dodson, R. O. Beard, B. D. Harrison and Professor Halsey.

The committee asked that the report be referred to the Council for action and recommendation as to whether the committee shall be continued, and it was so done.

REPORT OF THE COMMITTEE ON TEACHING HYGIENE IN THE PUBLIC SCHOOLS; AND THE PRESENT TEACHING OF DOMESTIC SCIENCE AND NATURE STUDY IN PUBLIC SCHOOLS, SO FAR AS THESE BRANCHES INCLUDE TEACHING HYGIENE.

This report was read by DR. HELEN C. PUTNAM, Providence, R. I., the other two members of the committee being Dr. Edward Jackson, Colorado, and Dr. George G. Groff, Pennsylvania.

Over seventy classes in domestic science in eighteen different cities were visited, and about as many in

nature study, in elementary, high, normal and special public schools.

Last year, in its report on the laws and on nearly one hundred textbooks in physiology and hygiene, written for children since 1882, the committee selected the latest and best books for special examination, to learn the possibilities and aims of these books. For the same reasons, in reporting the teaching of hygiene through domestic science and science teaching, the best programs of work were outlined, with brief details of the differences between these and the larger number of less efficient programs. The actual practice of principles of hygiene in domestic science and in the actual observation of biologic details and physical phenomena in the teaching of the sciences, called nature study in elementary schools, were briefly compared with the method of memorizing from books and talks. The larger range of work covered in the former classes was also noted.

The committee reserved its recommendations until it had reported on the other direct methods of teaching hygiene in the public schools.

ALTRUISM IN THE MEDICAL PROFESSION.

This was the title of the President's address, delivered by DR. WINFIELD S. HALL, Chicago. The higher the order of altruism, the fewer there were who attained to it. Voluntary sacrifice of life in order that other lives might be saved was the highest order of altruism. This height of sacrifice had been attained by a comparatively small number only; a number, however, that should include the names of many unknown heroes who had gone to their deaths while ministering to the sick in plague-stricken places, leaving no record of their heroism. The speaker cited examples from the ranks of the medical profession, covering a period from the founding of the profession to the present time. Enduring fame in the medical profession could be won through altruism only. If fame rested upon altruism, then would such names as William Stokes, Samuel D. Gross and Nathan Smith Davis have a fame which would endure through the ages.

Organized for the purpose of advancing the standards of medical education, of advancing the boundaries of medical science, of elevating the profession and of preventing disease, the work of the American Academy of Medicine had been altruistic from the time of its organization to the present. The field of its activities was ever-widening, and always along altruistic lines.

If he were asked to make a general recommendation, it would be that the Academy accept as its field of endeavor the altruistic responsibilities and activities of the medical profession, definitely outlining a program of research to be prosecuted along various lines as education, school hygiene, state medicine, ethics, etc. This research should be followed by carefully directed and persistent efforts to accomplish that which the research revealed to be advantageous to society.

Following the President's address, DR. CASEY A. WOOD, Chicago, delivered an interesting lecture on

THE EYES AND EYESIGHT OF THE LOWER ANIMALS,

which was illustrated by numerous colored stereopticon slides.

RECREATION IN ITS EFFECTS UPON THE NERVOUS SYSTEM.

DR. WILLIAM JAMES HERDMAN, Ann Arbor, Mich., stated that the practical methods by which suitable recreations were to be selected to meet the requirements of special classes or individuals would vary as taste, occupations and opportunities varied. From

the complexity of occupations in which people engaged there resulted the greatest variety of channels through which the store of nervous energy was depleted. Outdoor plays and games, requiring some skill, such as boating, fishing, swimming, skating, horseback riding, gardening, tool work and the like, were of much more recreative value than any of the artificial gymnastics which had no purpose nor incentive beyond the movement itself. For the brain worker the way was open to innumerable recreations, and the opportunity for choice and the possibility of varying their character, at will, would make the problem of healthful living an easy one if any man would but cultivate a sufficient variety of interests, so that when one channel of activity was for any reason closed to him, as a relief from necessary work, he had but to choose another. The practical result in this was seen when the statistics of health and longevity of the brain worker and of the muscle worker were compared. The researches of Dr. Beard and others had shown that brain workers not only lived from fourteen to twenty years longer than muscle workers, but that their health was more uniformly good and their stature of larger average. When mankind was once emancipated from the conception that honest work was contemptible drudgery, and learned to recognize the pleasures and recompense it had in store when rightly apprehended, which meant that the work selected must be suited to individual capacities and tastes, and when greed and selfishness gave place to a spirit of mutual helpfulness, the problem of recreation would be solved.

THE PHYSIOLOGY OF RECREATION.

DR. GEORGE W. McCASKEY, Fort Wayne, Ind., said that the primary and predominant factor in practically all forms of recreation was the psychical one. Although the influences of the mind over the body were recognized in a general way, it was fully comprehended by few, if any. The sudden change from a state of extreme depression and misery, with perfectly distinct physical suffering, to one of buoyancy and exultation, with entire forgetfulness of self as a result of a change of emotion was a not unfamiliar experience in the lives of most people.

As an illustration of the broad effects of mental impression in general, he mentioned the case of an attorney under his observation, whose digestion after considerable improvement remained more or less distressing in spite of all he could do for his relief which included the treatment of a local stomach disease by suitable methods, careful regulation of diet, gymnastics and a liberal amount of outdoor exercise. This gentleman would go to a little lake forty miles away, the very first meal that he would eat there, long before there could be any possible effect of exercise, atmospheric change, etc., would be digested without the slightest disturbance or even consciousness on his part, and this would continue until his return to the city, when the old conditions would be immediately resumed. If the various forms of recreation were closely scrutinized, it would, he thought, be found that those diversions and amusements which produced the promptest and most brilliant effects upon both the mental and physical states of those who participated were precisely those in which the psychical impression was the strongest. The first requisite in what might be termed successful recreation was a complete divorce from self, a complete submergence of self-consciousness, which inhibited that everlasting introspection of our physical selves which was the foundation of half the morbidity of the world. How this could best be done was a problem for the individual and depended upon his age, sex, social status, intellectual development

and other factors which went to make up the complete ego.

The next invited attention to the purely physical or mechanical aspects of many forms of recreation; in other words, the factor of muscular exercise, and said that the systematic introduction into our lives of such recreation as was suited to individual needs should be the rational aim of all, and a proper understanding of the physiological laws and facts which underlay the whole subject could not be otherwise than helpful. He concluded with the admonition of Virgil that "rural recreations abroad, and looks at home, are the innocent pleasures of a man who is early wise."

RECREATION AS A SOCIAL FACTOR.

DR. DWENY C. HAWLEY, Burlington, Vt., said that while work was necessary and enabling, and was the law the universe obeyed; refreshment of the strength and spirits after toil was likewise a necessity, which found expression in the natural cravings of the social instinct and in the general desire for diversion and amusement. The social instinct demanded satisfaction, and would find it in recreation and amusement, which was either beneficial and uplifting, or injurious and degrading. Teachers should realize the importance of recreation and use the opportunities which their positions afforded in influencing the children under their care to seek recreation which recreates, and amusements which would bring the most perfect joy.

THE RELATION OF RECREATION TO EDUCATION.

MR. R. K. ROW, superintendent of schools, Berwyn, Ill., presented a brief statement of the recognized psycho-physical theories of play, and then discussed the special educative functions of recreative activities. Out-of-door games, plays and recreations were the best means of physical education. He referred to the forms of recreation which involved considerable intellectual activity, and said co-operative games promoted social education. They developed the qualities of leadership, self-reliance, self-control and the spirit of co-operation in social groups. Recreation was a very large and vital factor in esthetic education. Recreative activities had also important ethical functions.

CEREMONIALS AND FEASTS IN THE EDUCATION OF LARGER GROUPS OF INDIVIDUALS.

DR. BAYARD HOLMES, Chicago, said that the value of the pageant had been well recognized by every organization which had aimed to secure a control over public opinion and public life. The educational and social functions of the pageant could not be confined to any one class or age. It had a use for every class and for every member of society. For the youth, there was one of the great liberty and freedom from restraint. For the young adult it furnished the occasion for important amenities. For the senior, the prime of life, abundant opportunity was given for the display of success in duty and every activity of life. The social, the economic, and the political success could be satisfactorily exhibited within the column of affluence or adversity. Even the aged might receive the satisfaction of an honorable defeat. But the extent of the influence of the pageant and the social and festive festival reached farther, it could be said, and aged every joy giving activity of life.

MEDICAL FEATURES OF CERTAIN RECREATIONS.

DR. CARL H. VON KRIES, Chicago, presented an exhaustive and scholarly paper on the medical features contained a history of the development of the various sports. The author described the medical features of

of writing, mentioned its age, the date of transcription, the contents of the papyrus and gave a description of the diseases mentioned in it and their treatment. He likewise mentioned the transcription of the papyrus from hieratic to hieroglyphics, and from the latter into a Latin glossary. He called attention to the various medical papyri now in existence, and referred to the similarity of ancient Egyptian medicine to the Mosaic. He discussed post-Biblical medicine in its relation to the time of Hippocrates, following up with the Mishna and Homer, giving a complete history of prehistoric medicine from about five thousand years before the Christian era down to the time of Hippocrates, with a translation of the same into English by the author.

OFFICERS.

The following officers were elected for the ensuing year: President, Dr. Donly C. Hawley, Burlington, Vt.; Vice-Presidents, Dr. Helen C. Putnam, Providence, R. I.; Dr. C. W. McCaskey, Fort Wayne, Ind.; Dr. Henry B. Favill, Chicago; Dr. James T. Searcy, Tuscaloosa, Ala.; Secretary-Treasurer, Dr. Charles McIntire, Easton, Penn.; Assistant Secretary, Dr. Samuel C. Stanton, Chicago.

Boston, Mass., was selected as the place for holding the next annual meeting; time, June 2-4, 1906.

Recent Literature.

Manual of Chemistry. By W. SIMON, Ph.D., M.D., Professor of Chemistry in the College of Physicians and Surgeons of Baltimore, and in the Baltimore College of Dental Surgery; Emeritus Professor in the Maryland College of Pharmacy, Department of the University of Maryland. Eighth edition, thoroughly revised. Philadelphia and New York: Lea Brothers & Co. 1905.

The previous editions of this work have been reviewed by us, and the valuable features of the book commented upon. This eighth edition differs very little from the seventh, except that the new United States Pharmacopœia has rendered a few changes and additions necessary. Several of the chapters on organic chemistry have been rewritten and made to conform to modern views. The subject of dental metallurgy has been given more attention, and a few changes have been made in the colored plates. The book is a good one for beginners in chemistry and specially designed for students of medicine, pharmacy and dentistry.

The Pharmacopœia of the United States of America. Eighth decennial revision. By authority of the United States Pharmacopœial Convention held at Washington, A. D. 1900. Revised by the Committee of Revision and published by the Board of Trustees. Official from Sept. 1, 1905. Philadelphia: P. Blakiston's Son & Co. 1905.

The eighth decennial revision of the United States Pharmacopœia appears as a volume of 692 pages, including the index. In arrangement and

subject matter it does not differ from previous editions. Liberal revision has, however, been made in the work of classifying and arranging the drugs to meet the advance in knowledge. The number of articles, test solutions and assays in the present Pharmacopœia as compared with that of 1890 shows an increase of forty articles. Of the articles previously official, 151 have been discarded, whereas 117 new ones have been introduced. In the present volume there are 958 articles in the text, 155 test solutions and volumetric solutions, 149 volumetric assays, and 35 gravimetric assays. In the Pharmacopœia of 1890 there were 994 articles in the text, 135 test solutions and volumetric solutions, 114 volumetric assays and 14 gravimetric assays. The subject matter is well arranged and easy of reference.

Static, High-Frequency, Radio-Photo and Radium Therapy. By DR. WILLIAM HARVEY KING. 291 pages. Boericke and Runyon. 1905.

Dr. King, who is the "Head of Clinic of Physical Therapeutics and Visiting Electro-Therapist at the Flower Hospital," states in his preface that "this work covers the subjects given in the title only and does not claim to be a complete treatise on electro-therapy." The book may be divided into three parts. In the first the author describes the various kinds of apparatus used; in the second the physics and physiology, while in the third he takes up the therapeutic application of the different methods.

Dr. King states also that he has aimed at conciseness. It has often happened that other authors with this same aim have attained their object but in so doing have destroyed the value of their work by a resulting lack of clearness and coherence. Dr. King, however, has avoided this sacrifice and has given us a book which is at once concise, coherent and intelligible. When one considers the breadth of the field which the subjects under discussion cover, his success in condensation becomes the more marked. The essential points in each subject are given clearly and in so few words that each one gains emphasis from the pruning. The author's statements are often dogmatic but that is to be expected in a work of this size as the limited space naturally forbids any extended discussion. Yet the writer has shown on the whole the conservatism for which he has striven. Further, the dogmatism is in a measure forced upon him by his desire, expressed in the preface, to adapt the book to the use of the busy man. Such a man must have his facts served up with the fewest possible qualifying phrases. Other workers in the subjects treated will, of course, object to many of Dr. King's conclusions, for even he says that there are many things to be worked out before any one can speak with final authority. Nevertheless, Dr. King's views may be considered fair and, even if not always acceptable to every one, they will at least serve as good points of departure for further research. The book, in our opinion, will be found readable and instructive.

same direction which has already borne much practical fruit.

In general, what we need to do in our overstocked out-patient departments is to systematize our work and give to each patient the maximum of benefit which can be derived from a single hasty hospital visit. The plan of forming classes of certain allied types of disease has been proved feasible and should be more widely practised. We have no doubt that the results would be similar to those attained in the tuberculosis classes, although possibly less striking. The contact of patient with patient, the stimulus toward carrying out directions and the feeling of fellowship which the class spirit engenders, should all be of service toward the attainment of the final result. The possible loss of the individual element in treatment would be a smaller evil than are many of the defects of our present system. At least, the experiment is worth trying.

IDENTIFICATION AND AUTOPSY OF THE BODY OF PAUL JONES.

The unusual interest which was aroused by the discovery, identification and transference of the body of Paul Jones from France to America is being revived again through the medical press. The story of the disposal of the body in a lead coffin and its recovery and identification after a period of one hundred and thirteen years, is generally known. Following the directions given in a plan which the searchers were able to secure, two coffins were finally found at a depth of sixteen feet beneath a house, one of which was found to contain the almost perfectly preserved body of Paul Jones, from which it was not difficult to make absolute identification by certain initials on the clothing and physical characteristics based upon historical details and upon the examination of two busts attributed to Houdin. The body was completely packed in straw, and was of a brownish black color, in an excellent state of preservation. In general, the appearance was that of a mummy, but the soft parts were still soft. In appearance and odor the body was similar to an old anatomical preparation long preserved in alcohol. A detailed description of the methods taken to establish the identity of the body is given in the February number of the *Edinburgh Medical Journal*, in turn taken from a recent number of the *Revue d'Ecole d'Anthropologie*, which serves as an

admirable example of modern scientific method. The combination of the evidence derived from various sources leaves no doubt whatever of the correctness of the ultimate conclusion that the body of Paul Jones had actually been recovered.

These facts have received wide comment, but so far as we are aware, the post-mortem findings have not been hitherto published, which certainly present a unique example of the possibilities of pathological research. It was known that during life Paul Jones had suffered from pulmonary disorder, and also that he probably had serious disease of the kidneys. We wish here merely to call attention to the results of the histological examination of the organs. The extraordinary fact was revealed that this histological examination gave practically as good results as if made immediately post-mortem. The lung tissue showed areas characteristic of bronchopneumonia, but Professor Cornil, who made the examination, failed to find giant cells or tubercle bacilli by the usual staining methods. There was distinct evidence of chronic interstitial nephritis, as indicated by sclerotic areas corresponding with glomeruli and thickened vessel walls. The liver was normal and gave most excellent sections. The report furthermore makes the following statement:

"On the surface of the skin, as well as of the viscera, but more especially on the lower limbs and surfaces of the lungs, small, white firm masses were observed. These proved on examination to be masses of crystals formed in the bundles of delicate needles characteristic of tyrosine, and also small round bodies, consisting probably of leucine. In order to explain the production of these crystals, we must suppose that between the time when the body was placed in the alcoholic preserving fluid and the period when the fluid had become imbibed into the various viscera, a sort of autolysis took place in the interior of the organs, which, in a manner similar to the digestion of albuminoid matters by diastases, gave rise to the formation of tyrosine. This interesting observation is worthy of being recorded along with the curious facts, wholly unexpected, it must be admitted, which the post-mortem examination on this historic body revealed. As we have seen, the results of the histological examination were in complete accordance with the clinical symptoms present during the last years of Paul Jones's life."

With this it is fitting that the body of Paul Jones should be finally and forever laid at rest. It is matter for congratulation that he has finally been interred in the land of his adoption, with all possible civic and military honors.

A POSSIBLE EXCESS OF ZEAL.

While recognizing the absolute importance of legislation directed against impure food, and commending all efforts toward the abatement of the evil, it must be admitted that a *reductio ad absurdum* is not an impossibility in this as in other matters of vital concern. Dr. H. W. Wiley, whose enthusiasm for reform we recognize and applaud possibly oversteps the mark of calm wisdom in his recent effort to deprive raspberry vinegar of its time-honored name. A New York daily contemporary quotes the decision as follows:

"A shipment of food product has been offered for importation labelled 'raspberry vinegar.' On notice that it was held for inspection, a representative of the importer appeared and stated that the substance was not a vinegar, but a drink, and intended to be used as a beverage. In this case the material is held to be misbranded, as a vinegar is never intended for a beverage, but only as a condiment.

"Notice is given that after May 1, 1906, importations of this description, or similar thereto, will not be admitted if misbranded in the manner mentioned. The name of the article, if descriptive, must indicate its true character. It is suggested that the term 'raspberry beverage' is a suitable designation. It will be held, however, that if so labelled, it must be a beverage made solely from raspberries or raspberry juice, and not preserved with any substance unmentioned on the label, except sugar, vinegar, or spices. Any substance added to such a product must not be injurious to health nor in violation of the laws of the country whence it comes."

Our contemporary thinks this is unnecessary, and we confess, if the report is correct, we are inclined to agree with him. The literalness of the terminology carries us too far. As our contemporary somewhat jocularly remarks, the term raspberry shrub "that simple potation of our boyhood" violates this decision. And the difficulties which are forced upon us grow as we contemplate other possibilities. We certainly wish absolutely pure food and no deception, but it is unwise to expose to the possibility of ridicule a movement which should receive the serious backing of every right minded person.

MEDICAL NOTES.

INFECTIOUS DISEASE AND PULLMAN CARS.

It is reported that the Pullman Car Company has gained its case before the Supreme Court of Alabama in its contention that it has the right to exclude from its cars persons with contagious or infectious disease. This decision grew out of

a case in which a passenger claimed damages because of his removal from a car of the Pullman Company. He won his case in the lower court, but this decision was reversed by the Supreme Court.

REPORT OF THE ADIRONDACK SANITARIUM. — The twenty-first annual report of the Adirondack Cottage Sanitarium has been published together with a medical supplement prepared by Dr. Lawrason Brown in accordance with the suggestion of the National Association for the Study and Prevention of Tuberculosis. The wide reputation which this sanitarium has obtained is demonstrated by the fact that patients discharged during the past year came from 20 states of this country and Canada, a total of 182. The various details of organization which have been developing during the past few years have been carried further during the past year with apparent benefit. Dr. Brown's supplement is a valuable statistical statement in tabular form of the results of treatment in a large number of patients.

WIDENER MEMORIAL HOME FOR CRIPPLED CHILDREN. — At the formal opening of the Widener Home for Crippled Children in Philadelphia, which occurred this week, it was announced that Mr. Widener, who had already given two million dollars for the building of the institution, had donated three million dollars more as a fund for maintenance. Dr. De Forest Willard made an address on the occasion of the opening of the hospital and stated the object of the institution to be as follows:

"For crippled and deformed minors, without distinction of creed, nationality or sex, to supplement the work of hospitals, to strengthen and renew the weak ones, and then to educate them into habits of industry, order, cleanliness, self-respect and self-reliance, to apply such mental, moral and religious training as will render them true, honorable, useful and self-sustaining members of the community."

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON.

For the week ending at noon, March 7, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 12, scarlatina 19, typhoid fever 1, measles 186, tuberculosis 80, smallpox 0.

The death-rate of the reported deaths for the week ending March 7, 1906, was 20.14.

BOSTON MORTALITY STATISTICS. — For total number of deaths reported to the Board of Health for the week ending Saturday, March 3, 1906

was 242, against 230 the corresponding week of last year, showing an increase of 12 deaths and making the death-rate for the week 21.20. Of this number 125 were males and 117 were females; 228 were white and 14 colored; 145 were born in the United States, 92 in foreign countries and 5 unknown; 45 were of American parentage, 164 of foreign parentage and 33 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 40 cases and 5 deaths; scarlatina, 12 cases and no deaths; typhoid fever, 9 cases and 1 death; measles, 207 cases and 3 deaths; tuberculosis, 84 cases and 29 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 49, whooping cough 1, heart disease 32, bronchitis 8 and marasmus 7. There were 7 deaths from violent causes. The number of children who died under one year was 47; the number under five years, 72. The number of persons who died over sixty years of age was 50. The deaths in public institutions were 79.

There were 2 cases and 3 deaths reported from cerebrospinal meningitis during the week.

"THE LION AND THE LAMB." — The allopathic lion and the homeopathic lamb have dined together, and nothing detrimental to either party happened. The occasion would have been perfect if, instead of touching glasses, the brethren had exchanged pills. — *Boston Herald*.

THE INDUCEMENTS TO ENTER THE NAVAL MEDICAL SERVICE. — Medical Director R. A. Marmon, U. S. N., president of the Naval Medical Examining Board, will give an address at the Harvard Medical School, in Lecture Room E, on Monday, March 12, at 8 P.M. The subject of the address will be "The Inducements which the Naval Medical Service Now Holds out to Young Men under Thirty Years of Age."

CONSUMPTIVES' HOSPITAL TRUSTEES. — Subject to confirmation by the Board of Aldermen, Mayor Fitzgerald has made the following appointments as trustees of the proposed Consumptives' Hospital in Boston: Edward F. McSweeney for five years, Miss Elizabeth A. Power for four years, Dr. James J. Minot for four years, Isabel Hyams for three years, John E. Potts and Dr. John F. O'Brien for two years and Herbert F. Price for one year. These trustees are empowered to expend \$150,000 ordered on July 3, 1901, but which has never been used. Mayor Collins was of the opinion that the amount was too small to begin an enterprise, the expense of conducting

which would be very considerable. There has from the first been a difference of opinion on this point.

NEW YORK.

PAID ADMITTING PHYSICIANS. — As the result of action taken at a meeting of the Board of Trustees, held Feb. 28, Bellevue Hospital will hereafter have four paid physicians for its reception ward. They will receive a salary of \$600, and serve in four-hour tours of duty. Up to the present time the work of admitting patients has devolved upon the regular internes of the hospital.

DIPHTHERIA AT BELLEVUE. — Several cases of diphtheria have developed in Ward 31 of Bellevue Hospital, devoted to children. One of the house staff, Dr. I. O. Woodruff, Jr., who had charge of the ward, contracted the disease and has been removed to the Minturn Hospital for Scarlet Fever and Diphtheria Patients. The infection is thought to have been carried to the ward by a child, seven years old, who was admitted from St. Vincent's Hospital with the diagnosis of cerebrospinal meningitis.

A BILL FOR LICENSING OSTEOPATHS. — The osteopaths have again renewed their efforts to get the legislature to recognize their practice, and on Feb. 28 a public hearing was given at Albany before the Senate Judiciary Committee on the Davis bill, which creates an osteopath examining board under the regents of the State University. Among those who spoke in opposition to the bill were Dr. Algernon T. Bristow of Brooklyn, ex-president of the State Medical Society; Drs. Abraham Jacobi, Edward D. Fisher and Frank Van Fleet, of Manhattan; Dr. Moriarity of Saratoga, and Edward O'Brien, attorney for the Erie County Medical Society. They contended that the bill as framed would give the persons now practising osteopathy recognition as physicians, without any adequate medical education. The only advocates of the measure were four osteopaths from different cities of the state.

Miscellany.

EPIDEMIC CEREBROSPINAL MENINGITIS; CLINICAL REPORT AND ANALYSIS OF SPECIAL SYMPTOMS IN THIRTY CASES, WITH REMARKS ON THE TREATMENT.

WILLIAM M. LESZYNSKY, *Medical Record* (March 3), presents in this paper the complete records of thirty patients. In all but one of these the diagnosis was confirmed by the demonstration of the *Diplococcus intracellularis meningitidis*.

gilitis in the cerebrospinal fluid. In this case, lumbar puncture resulted in a "dry tap"; nevertheless, more than the usual number of symptoms were present. Nearly all types of the disease are represented in this series of cases. Of the 30 patients, 17 were males and 13 were females. Fifteen recovered and 15 died, a mortality of 50%. Three children were of one family (two died), and two sisters were of another (one died). One boy, seven years old, died on the three hundred and seventh day. A boy thirteen years old, who recovered and was discharged, was readmitted six weeks later with another attack, from which he completely recovered. The duration of the disease in the fatal cases at the time of admission averaged about five days. The only fatal visceral complication was pulmonary edema. The writer declares that this is *par excellence* a disease of the nervous system. Whatever may be the sequelae, they are generally secondary to alterations in the nerve structures. The writer gives an analysis of a number of special symptoms: herpetic and petechial eruptions; muscular rigidity; loss of control of the bladder and rectum; the condition of the knee jerks; Kernig's sign; the Babinski plantar reflex; facial paralysis; deafness, and eye symptoms. The prognosis in this disease is frequently a most perplexing problem, especially during its early period. Most important features in the treatment are good nursing and proper feeding. Lumbar puncture was performed in each one of these cases once or oftener for either diagnostic or therapeutic purposes, and there were no unpleasant results. When the patients were restless or noisy, chloroform was used. A Quincke needle was generally employed.

THE BOSTON SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

THE Boston session of the American Medical Association will be the largest ever held. There is no doubt of it. It will be forty-one years since the Association met in New England, and the historical attractions will, of themselves, be sufficient to draw many to the meeting. The members of the profession from New York city and state — will go as they have never gone before. From the South, the Southwest and the extreme West there are more inquiries about railroad rates, accommodations at Boston, etc. than in any other year. New England itself is also being heard from in a way to show that it will be unusually well represented at the session. The officers of nearly all the sections report filled programs unusually early and more evidence of interest in scientific work. While the passenger associations have not acted definitely, those in authority have given assurances that half rates will prevail, with the extension of time to those who want to extend their visit in New England. It is hoped that provisions will be made to accommodate those who want to go by one route — say by the lakes — and return by

another. Many foreigners have already accepted invitations to attend, among them Prof. Trendelenburg, Leipzig, Germany; Mr. Reginald Harrison, London, England; Prof. von Rosthorn, Heidelberg, Germany; Prof. Dührssen, Berlin, Germany, and Prof. von Frey, Würzburg, Germany. Hence we repeat: The Boston session of the American Medical Association will be the largest ever held, and the Boston people know it and are acting accordingly. Committees have been working for months making preparations, and they promise good accommodations and a thoroughly interesting and profitable time to all who attend. — *Journal American Medical Association*, March 3.

OFFICIAL ORGAN OF THE NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS.

THE *Journal of the Outdoor Life*, which is published at the Adirondack Cottage Sanitarium, Trudeau, N. Y. (Saranac Lake), and which has just entered upon its third year, has been made the official organ of the National Association for the Study and Prevention of Tuberculosis. The *Journal of the Outdoor Life* deals with the outdoor treatment of tuberculosis in an intelligent and scientific manner. It does not advocate self-treatment by the laity or attempt to supplant personal medical advice. It aims to point out the more common pitfalls that beset the unwary health seeker and to awaken in its readers a healthful interest in an outdoor life. It advocates competent medical supervision, fresh air, nourishing food and carefully regulated exercise.

"THE PURGATION OF THERAPEUTICS."

New York, March 3, 1906.

My Editor: In view of your editorial with a view to submit what follows:

I. There are unquestionably a few proprietary medicines of great and remedial value by reason of special pharmaceutical knowledge, which has been employed to obtain the alkaloids or extracts from a particular plant. The individual to whom this process has become known, after much work and investigation, is not bound contractually to divulge his secret, admitted his character as above approach, as proven by his long good service, on the judgment of his peers. And I am bound morally to the use of this preparation for my ill patient if I know of and equally reliable and effective agent in the treatment of his case? And if this be true, why may I not say so?

II. There are compounds which must exert their purgative effect through other. I have discovered no preparation for certain symptoms. It is my own, or belongs to a particular drug firm whose honor and reputation among pharmacists is established. If it be a new compound, it is impossible always to recall its process, and I am bound. And in order to make use of it without which my patient must be regarded as a particular drug firm, I am bound to name which shall designate it to the drug firm. It belongs to the firm, I prescribe with the name of the firm, I have given it.

Very truly yours,

BRENDEN HARRISON.

OFFICIAL LIST OF THE CHANGES OF STATION AND DUTIES OF COMMISSIONED AND NON-COMMISSIONED OFFICERS OF THE PUBLIC HEALTH AND MARINE HOSPITAL SERVICE FOR THE SEVEN DAYS ENDING FEBRUARY 28, 1906.

PETTES, W. J., assistant surgeon-general. Granted leave of absence for 1 month from March 1, 1906. Feb. 27, 1906.

MAGRUDER, G. M., surgeon. Upon expiration of leave of absence to proceed to Portland, Ore., and assume command of the service. Feb. 23, 1906.

NYDEGGER, J. A., passed assistant surgeon. To proceed to Perth Amboy, N. J., for special temporary duty, upon completion of which to rejoin station at Stapleton, N. Y. Feb. 26, 1906.

OFFER, L. E., passed assistant surgeon. Granted one day's leave of absence under paragraph 189 of the regulations. Dec. 12, 1905.

KOKN, W. A., passed assistant surgeon. Granted leave of absence for fourteen days from March 2, 1906. Feb. 26, 1906.

LONG, J. D., passed assistant surgeon. Granted seven days' leave of absence in December, 1905, under paragraph 191 of the regulations.

BURKHALLER, J. T., passed assistant surgeon. Upon being relieved by Assistant Surgeon R. D. Spratt to proceed to Ellis Island, N. Y., reporting to the medical officer in command for duty. Feb. 21, 1906.

SPRATT, R. D., assistant surgeon. Relieved from temporary duty at Mobile, Ala., and directed to proceed to Brunswick Quarantine Station and assume command of the Service, relieving Passed Assistant Surgeon J. T. Burkhalter. Feb. 21, 1906.

DELAGADO, J. M., acting assistant surgeon. Granted four days' leave of absence from Feb. 13, 1906, under paragraph 210 of the regulations.

KURTZ, W. E., acting assistant surgeon. Granted leave of absence for thirty days from Jan. 1, 1906, on account of sickness. Feb. 21, 1906.

RICHARDSON, N. D., acting assistant surgeon. Granted leave of absence for fourteen days from Jan. 27, 1906, on account of sickness. Feb. 21, 1906.

SAITFORD, M. V., acting assistant surgeon. Granted three days' leave of absence from Feb. 17, 1906, under paragraph 210 of the regulations.

O'GORMAN, T. V., pharmacist. Relieved from duty at New Orleans, La., and directed to proceed to Memphis, Tenn., reporting to the medical officer in command for duty and assignment to quarters. Feb. 26, 1906.

SCOTT, E. B., pharmacist. Granted two days' leave of absence from Feb. 21, 1906, under paragraph 210 of the regulations.

BOARD CONVENED.

Board convened to meet at the Bureau, Washington, D. C., Feb. 24, 1906, for the purpose of making a physical examination of an officer of the Revenue-Cutter Service. Detail for the Board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon J. W. Trask, recorder.

SOCIETY NOTICES.

AMERICAN MEDICAL ASSOCIATION CHORUS.—I have been asked to announce to eighty voices a chorus of physicians (who have sung together for some years past at the annual dinner of the Massachusetts Medical Society) in order that we may furnish some music at the President's Reception during the coming meeting of the American Medical Association in June, 5-8. We have now forty-five names on our chorus list. We must have five or six rehearsals between now and June. Anyone knowing of any good singers in the profession (graduates or undergraduates) will please suggest names (their own or others) to

RICHARD C. CABOT, M.D.,
190 Marlboro St., Boston.

THE AMERICAN LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL SOCIETY.—The twelfth annual meeting of the American Laryngological, Rhinological and Otolological Society will be held under the presidency of Dr. Jas. E. Logan, at Kansas City, Mo., on Monday, Tuesday and Wednesday, June 11, 12 and 13, 1906. The Council respectfully calls your attention to the prizes which have been offered by the following members of the Society: J. E. Sheppard, M.D., Topic: "The Best Classification of Non-suppurative Affections of the Middle Ear," the same to be based so far as possible on pathological research. Prize, \$100.00. Dr. Braden Kyle, M.D., Topic: "Atrophic Rhinitis." Prize, \$100.00. Charles W. Richardson, M.D., Topic: "What Operative Treatment Offers the Best Results for the Cure of Chronic Suppurative Frontal Sinusitis." Prize, \$100.00. Norval H. Pierce, M.D., Topic: "Original Work on Rarification of the Labyrinthine Capsule." Prize, \$100.00. Edward B. Dench, M.D., Topic: "Chronic Non-suppurative Inflammation of the Middle Ear." Prize, \$100.00.

The above named prizes may be competed for by members of Society only and competitors are requested to present their papers to the Society will enter into a written competition both for the prizes and for the original Research Fund.

The Council further announces that the Society holds for the encouragement of research a fund of \$500.00, the whole or a portion of which may be awarded at the discretion of the Council, to any of the Society's members presenting an essay embodying original work in subjects pertaining to laryngology, rhinology or otology. The Council reserves the right to make no award, if in its opinion the essays are of insufficient merit. All essays submitted must be anonymous, being designated by a motto or device, the writer's name and address accompanying the essay in a sealed envelope, inscribed with the same motto or motto as the essay. It is hoped that many members of the Society will enter into this competitive competition both for the prizes and for the original Research Fund.

WENDELL C. PHILLIPS, M.D., Secretary.

THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The regular meeting of the society will be held in Sprague Hall, Medical Library Building, on Monday March 12, 1906, at 8:15 P. M. Program: "Some Cases of Septic Infection," Dr. E. Channing Stowell. "Remarks on Joint Infections," Dr. Robert W. Lovett. "The Relation of the Histological Changes in the Tonsils to Systemic Infections," Dr. J. L. Goodale.

DANIEL FISKE JONES, M.D., Secretary.

RECENT DEATHS.

DR. WILLIAM P. DRAKE of New York died on March 1 from an over-dose of morphine, taken while suffering intensely from facial neuralgia. Dr. Drake was thirty-one years of age and was graduated from the medical department of the University of the City of New York in 1889. At the time of his death he was a medical examiner of the Prudential Life Insurance Company.

WARREN PERKINS BLAKE, M.D., M.M.S.S., died in Springfield, Feb. 15, 1906, aged forty-seven years.

JOHN HARRIS PETTEE, M.D., M.M.S.S., of Roxbury, died March 5, 1906, aged thirty-four years.

Original Articles.

ADENOMYOMA OF THE UTERUS. A REPORT OF FOUR CASES.

BY W. P. GRAYSON, M.D., BOSTON.

From the Laboratory of the Free Hospital for Women.

The four cases of adenomyoma occurring in the collection of uterine fibroids examined in the laboratory of the Free Hospital for Women the past three and one-half years are reported, first, because they represent a somewhat higher percentage of these tumors than is ordinarily found, and, secondly, because they illustrate in a very convincing way the somewhat doubtful histogenesis of these very interesting tumors.

The occurrence of four adenomyomata in a total of one hundred myomatous uteri is, as far as I can learn, unusual, and may be accounted for as a mere coincidence, the total number of cases examined being too small a figure upon which to base a perfectly authentic percentage. On the other hand, it may possibly be explained by the fact that it is customary in the Free Hospital laboratory to make a searching routine examination of all myomata, with the hope eventually to establish reliable figures for the occurrence of deviations from type in uterine fibroids, especially with reference to the presence of adenomatous inclusions and the frequency of sarcomatous degeneration. The cases here reported are especially instructive from a histological standpoint because they happen to represent the two distinct groups into which these tumors are to be classified with reference to their histogenesis and the careful study of them ought to clear up any existing doubt on this point.

Myomata of the uterus containing epithelial gland inclusions have long been observed, and numerous theories as to their origin have been propounded. Disterweg, Schröder, Ribbert, Ruge, Babes and others considered them ordinary myomata, which, beginning near the endometrium, cut off some of the glands, which thus remain included during the growth of the myoma. Hauser advanced the theory that the epithelial glands represent portions of Müller's ducts which have wandered from their normal position during embryonal life and have become included by the myoma during its development, and that therefore the growths represent a sort of mixed tumor. Other investigators believe the gland inclusions to represent branchings from cutaneous ducts. Ricker, in the study of hundreds of small fibroid myomata, observed that they were all alike in character and concluded for this reason that the gland inclusions could not have originated from the uterine mucous membrane. He assigned their origin to offshoots from Müller's ducts.

The well known monographs of von Recklinghausen, who made an extensive study of these interesting tumors, did much to clear up the doubt which existed as to their histogenesis. He pointed out that they might originate from two different sources, namely, the remains of the

Wolffian ducts or the uterine mucous membrane, thus dividing them into two distinct forms. The four cases here described represent the two groups described by von Recklinghausen, namely, that originating from the Wolffian ducts, and that from the uterine mucosa. Three of my cases belong to the first group.

CASES ORIGINATING FROM THE WOLFFIAN DUCTS.

Without detailing at too great length von Recklinghausen's description of these tumors it may be stated in brief that he found the following characteristics common. These adenomyomata occur only on the posterior wall of the uterus and at the tube angles, or on the cranial side of the interstitial portion of the tubes. They are frequently bilateral. They are not circumscribed like the ordinary fibroids, and never have a capsule about them, but, on the contrary, grow into the surrounding tissue, and were therefore called by him diffuse or infiltrating fibroids. He distinguished hard, soft, cystic and telangiectatic forms, and formulated that the harder and smaller tumors develop nearer the serosa. Microscopically, von Recklinghausen found that these tumors contain scattered gland inclusions having a decided tendency to become cystic; that the glands are lined with a simple cylindrical epithelium, sometimes ciliated, and that they are surrounded usually, but not always, by a cytogenous tissue. The origin of these structures is referred to the rests of the Wolffian bodies and especially to the distal portion of it called the paroöphoron. As proof of this, von Recklinghausen pointed out the presence in the glands of ciliated epithelium such as appears in other growths derived from the Wolffian body, for example, the paroövarian cysts. He also showed in some of his specimens that the glands represent a well defined communicating system, and described "secretory" and "collecting" tubules with ampullar dilatations, thus resembling closely the structure of the paroövarium. As further proof of their origin from the Wolffian body, he described in these adenomyomata pigment bodies and a compound duct, both characteristic appendages of the paroöphoron in the female and the organ of Gaddoli or the paraödynia in the male. The paroöphoron and paroödynia, according to the author, in the female at least, exist only at the distal end of the parametrium, and form two rudimentary appendages of the uterus.

Although some of the main details of the histology of these adenomyomata are taken from von Recklinghausen's monograph, it is to be understood that a considerable number of additional observations have been made by the author.

CASE I. Mrs. P., thirty-two years of age, a year without menses, due to the fact that she had for Women's Hospital, physicians, Dr. J. C. Allen, Dr. J. A. Allen, Dr. J. C. Allen, and Dr. J. C. Allen, and a course of treatment consisting of the use of ergot, with temporary relief. The diagnosis was peritonitis, and the operation was performed, resulting in the

of cutting the uterosacral ligaments in order to relieve the malposition of the uterus. In the course of the operation a hard mass about the size of a pigeon's egg was discovered lying low down on the posterior surface of the uterus at the level of the reflexion of the peritoneum from the uterus to the rectum. An attempt to enucleate this mass was met with much difficulty from the fact that it was growing diffusely into the surrounding tissue. So firmly was it imbedded in the tissues that in removing it an opening was made into the rectum, which was closed, and from which no later trouble arose. The patient made a good recovery and a later report stated that she had been cured of her symptoms. Microscopical examination showed the tumor to be made up of typical myomatous tissue, in which were scattered gland inclusions which varied greatly in size; some of them being small, while others were considerably dilated. The epithelium lining these glands varied from a low cuboidal character to a high columnar variety, on which cilia could be occasionally distinguished. The glands were of a dichotomous type. Surrounding most of the glands was a cytogenous tissue. This cytogenous tissue was more marked wherever the glands were more closely grouped. Some of the isolated glands were closely surrounded by myomatous tissue.

The essential features in this case were: First, occurrence in a uterus which presented developmental defects; second, occurrence on the posterior surface of the uterus though in an unusual position; third, diffuse character of the tumor; fourth, presence of branching gland structures lying in a bed of cytogenous tissue.

CASE II. Mrs. W., twenty-eight years of age; married six years, without children; entered the Free Hospital November, 1905, with a complaint of dysmenorrhea for twelve years. An entrance diagnosis of fibroids of the uterus was made. At the operation an intraligamentary parovarian cyst was found on the right side. This was removed. On the posterior wall of the uterus were seen two small, hard, subserous myomata, one lying on the cranial side of the fundus and a little to the right of the median line, the other lying just under the right tube angle. In attempting to enucleate these myomata they were found so diffuse and so firmly infiltrating the surrounding tissue that it was necessary to dissect them out. The position of these small myomata, together with their marked diffuseness of growth, made it possible to diagnose them at once. This diagnosis was further confirmed by the appearance of the tube which showed a marked fibroid thickening on the cranial side of its interstitial portion. The ovary on the left side was good, and as the patient had been faithfully promised that at least one tube and ovary should be left her on account of her great desire to have children, it was decided not to remove the tube on this side, this being justifiable from the evidence of authorities of the non-malignancy of these tumors. There is no doubt whatever, in view of the further microscopical findings in the myomata of the right horn, that this tube thickening on the left side was a small adenomyoma of the tube corresponding to the type described by von Recklinhausen.

Microscopical examination of the two small tumors showed the following: The growth was chiefly made up of typical myomatous tissue, in which were scattered gland inclusions, both isolated and in groups, lined for the most part by columnar, ciliated epithelium. In places the gland structures were grouped together, uniform in size and running in parallel directions. The entire group was imbedded in a mass of cytogenous tissue. Some of the glands showed a dichotomous branching. The isolated glands showed a tendency to ampullar dilatation.

The essential features in this case were: First, occurrence in connection with an intraligamentary cyst of developmental origin; second, characteristic position and diffuseness of the adenomyoma growing in connection with the fibroid enlargement of the base of the left tube, probably also an adenomyoma; third, characteristic tubules described by von Recklinhausen.

CASE III. Miss M., forty-three years of age, single, entered Free Hospital December, 1905, with a history of dysmenorrhea. Diagnosis at entrance examination, multiple, subserous fibroids. At the operation the uterus was found to be somewhat symmetrically enlarged on both sides and was removed. The specimen on being examined in the laboratory was found to be that of a septate uterus. At both tube angles were found diffuse myomatous growths in which could be seen on section small cysts. Microscopical examination of the tissue from these myomatous enlargements showed that these cysts were dilated gland inclusions having the same characteristic cylindrical, ciliated epithelium and imbedded in cytogenous tissue in the manner described in the two previous cases. In this case some of the sections were so cut that some of the glands could be seen to form long, slender tubules, while others were greatly dilated and cystic. No definite communicating system could be made out without serial sections. The cytogenous tissue in this case was much more marked than in either of the others and there were many areas of it in which no gland structures lay, the sections doubtless having just escaped them. The essential features in this case were: First, occurrence in a uterus showing other developmental defects; second, long, slender isolated tubules probably connecting with the dilated and cystic ampulla.

It will thus be seen that the tumors here described correspond in nearly every particular to the adenomyomata described by von Recklinhausen as deriving their origin from the Wolffian rests. The only part of the evidence which is incomplete is that in no instance could any suggestion of glomeruli be discovered whatsoever, although a most careful search for these bodies was made. The study of these three cases discloses an additional fact which is extremely suggestive and one which I think is not noted in the cases of other writers. In all three cases there occurred, in connection with the presence of adenomyomata, well marked developmental defects of some part of the pelvic organs. How frequently this faulty development may occur with adenomyomata it is impossible to state, but it may be well imagined that some such condition is probably frequent and possibly constant.

ADENOMYOMA ORIGINATING FROM THE UTERINE MUCOSA.

Of this form of adenomyoma, von Recklinhausen has much less to say. He, however, recognized it as a different species and, in general, characterized it as follows: The neoplasm usually grows from the entire circumference of the uterine canal. The gland inclusions in the myoma connect with the uterine mucosa and resemble them in every respect. They have a tendency to become cystic. They may arise

from the anterior wall of the uterus and even from the cervix.

Of this class of adenomyoma I have only one representative case, but this is a truly remarkable one. From the fact that I have found only one such case in one hundred myomatous uteri, and from the rather doubtful mention of them in literature, I am convinced that this form of tumor is rarer than the first group described, although this is a view which is not held by Abel. It will be seen that the type and general characteristics of this kind of tumor are so strikingly different from those already described that

CYTOGENOUS TISSUE.

Much has been said in the literature of these tumors concerning the importance of the cytogenous tissue in giving a clue to their histogenesis. Cytogenous tissue is a loose reticular tissue made up of round or spindle-shaped cells, which do not lie in close contiguity. It is found normally surrounding most gland elements, as, for example, in the uterine and intestinal mucosa. Many theories regarding the derivation of this tissue have been advanced; for example, Abel thinks that it may take part in the regeneration of the

ADENOMYOMA. GRAVES.

Adenomyoma originating from the uterine mucosa. The uterus is represented as having been opened along its anterior wall exposing the growth, which extrudes from the amputated cervix. Near the peripheral end of the tumor may be distinguished small cystic openings. The left tube, cut off near its base, shows the way in which it was dilated by the ingrowing carcinomatous mass.

but that they were ingrowths of the proliferating mesoplasm which were simply pushing their way into the openings of the tubes, taking the line of least resistance. The glandular structures found in this tumor evidently connected with the endometrial glands of the uterus and corresponded with them in general makeup.

The point of origin of this tumor, the appearance of the glands, the carcinomatous invasion from within outward and its general characteristics corresponding with the description of Von Recklinhausen form convincing proof that it derived its histogenesis from the endometrium.

The pedicle was at least six inches long and rather smaller than the little finger, and rotation had taken place so gradually that there was not the slightest evidence of strangulation. There were no adhesions to the walls of the tube or necrosis at the seat of torsion and the contents of the tube were clear and straw-colored. When the tumor was cut away and there was no tendency towards a return of the tumor. The ovary took no part in the torsion. I amitated the tube, leaving the ovary.

It was then found that the left tube, which was cut about the size and shape of a large egg and had a

adenomyoma of the tube corresponding to the type described by von Recklinhausen.

Microscopical examination of the two small tumors showed the following: The growth was chiefly made up of typical myomatous tissue, in which were scattered gland inclusions, both isolated and in groups, lined for the most part by columnar, ciliated epithelium. In places the gland structures were grouped together, unitary in size and running in parallel directions. The entire group was imbedded in a mass of cytogenous tissue. Some of the glands showed a dichotomous branching. The isolated glands showed a tendency to ampullar dilatation.

ADENOMYOMA ORIGINATING FROM THE UTERINE MUCOSA.

Of this form of adenomyoma, von Recklinhausen has much less to say. He, however, recognized it as a different species and, in general, characterized it as follows: The neoplasm usually grows from the entire circumference of the uterine canal. The gland inclusions in the myoma connect with the uterine mucosa and resemble them in every respect. They have a tendency to become cystic. They may arise

from the anterior wall of the uterus and even from the cervix.

Of this class of adenomyoma I have only one representative case, but this is a truly remarkable one. From the fact that I have found only one such case in one hundred myomatous uteri, and from the rather doubtful mention of them in literature, I am convinced that this form of tumor is rarer than the first group described, although this is a view which is not held by Abel. It will be seen that the type and general characteristics of this kind of tumor are so strikingly different from those already described that although necessarily included under the general heading of adenomyoma, it must be classified as a perfectly distinct species.

CASE IV. Miss M., thirty-eight years, single, admitted to the Free Hospital December, 1904, with a history of metrorrhagia. Entrance diagnosis was fibroid polyp of the uterus. The uterus at operation was found to be boggy and heavy and was removed by a supra-vaginal hysterectomy. The specimen on examination in the laboratory showed a large, soft uterus from which extended a rather soft, polypoid tumor from the amputated cervix. Section of the uterus into the canal showed that the tumor was growing from the circumference of the canal, though mostly from the posterior wall. On the surface of the tumor, especially at the periphery, were small cystic openings. The peripheral end of the tumor was much harder and firmer than the proximal attachment to the uterus, where it was extremely soft and friable. Microscopical examination showed the tumor to be made up of smooth, muscular tissue and proliferating gland tissue. In the distal portion of the tumor, namely, that extruding from the cervix, the muscular tissue was well marked, including, however, many glands which had a decided tendency to become cystic. These glands were lined with a low cuboidal epithelium and contained mucous secretions. There was little cytogenous tissue, however, the muscular tissue for the most part growing closely in contact with the basement membrane. Further examination of the tumor nearer its base showed the myomatous tissue to be much less in evidence, while glandular tissue was proliferating in great profusion, and the non-glandular substance became more and more cytogenous in character. The sections of the myometrium near the point of origin of the growth showed that the glands had actually invaded the wall of the uterus to at least one half its width and were adenocarcinomatous in character. The tubes were both dilated at the junction with the uterine horns and masses of soft, friable tissue were found within them. Microscopical examination, however, showed that these masses were not growing from the lining membrane of the tubes, which, though much dilated, preserved their integrity, but that they were ingrowths of the proliferating neoplasm which were simply pushing their way into the openings of the tubes, taking the line of least resistance. The glandular structures found in this tumor evidently connected with the endometrial glands of the uterus and corresponded with them in general makeup.

The point of origin of this tumor, the appearance of the glands, the carcinomatous invasion from within outward and its general characteristics corresponding with the description of von Recklinhausen form convincing proof that it derived its histogenesis from the endometrium.

CYTOTOGENOUS TISSUE.

Much has been said in the literature of these tumors concerning the importance of the cytogenous tissue in giving a clue to their histogenesis. Cytogenous tissue is a loose reticular tissue made up of round or spindle-shaped cells, which do not lie in close contiguity. It is found normally surrounding most gland elements, as, for example, in the uterine and intestinal mucosa. Many theories regarding the derivation of this tissue have been advanced; for example, Abel thinks that it may take part in the regeneration of the uterine epithelium and gives as a reason that the epithelial-like cells of the decidua result from the cytogenous tissue. Some authorities consider it a lymphatic tissue, while others consider it a hyperplasia of connective tissue or a developing muscle tissue.

The study of these reported cases of adenomyomata of the uterus and of the stroma of the endometrium under all conditions of change in the endometrium, convinces me that it is merely a modified muscular tissue and occurs in the uterus and in the myomatous neoplasms of the uterus, serving as a protective bed for delicate gland structures wherever they occur.

BILATERAL TORSION OF THE FALLOPIAN TUBES.*

BY MARGARET TORRICE, M.D., BOSTON.
Gynecologist to Carney Hospital and Boston Dispensary.

This paper is based upon the following case:

A. K., Carney Hospital, vol. xiv, p. 505. Twenty-nine. Married six years. Never pregnant. No history of gonorrhea to be obtained. Menstruation regular and not especially painful. One year ago treated for dull pain in left side, lasting a month. Nothing acute. No vomiting. Possibly slight fever at times. For last two months some pain for two days before menstruation.

Examination showed a somewhat vague mass to left of the normally placed uterus, consisting apparently of the slightly enlarged tube with adherent ovary, while behind and to the right was felt a tense, elastic and unadherent, though not very movable, tumor the size of a fist.

Diagnosis.—Left salpingitis and right hydrosalpinx.

At operation, Aug. 25, 1905, it was found that a cold, symmetrical, right hydrosalpinx was present, measuring 4 inches by 3 by 3, wedged rather tightly behind and to the right of the uterus. On tracing this tube up it was found that it had been rotated through 360° following the heads of which, as its originally upper surface had swung forwards and to the right. The pedicle was at least six inches long and rather smaller than the little finger, and rotation had taken place so gradually that there was not the slightest evidence of strangulation. There was no cohesiveness in the walls of the tube or necrosis at the seat of torsion and the contents of the tube were clear and straw-colored. When the tumor was opened up and there was no tendency towards a return of the torsion. The ovary took no part in the torsion. I am not sure if the tube, leaving the ovary.

It was then found that the left tube was twisted about the size and shape of a large thumb, and also

* Read before the Obstetrical Society of Boston, Jan. 22, 1906.

undergone torsion, but only to 180° and in the direction contrary to the hands of a watch, the upper surface swinging forward and to the left, and had also twisted so that the closed fimbriated end now pointed at the posterior aspect of the uterine cornu, thus both tubes following Küstner's law of ovarian axial rotation. But while in the case of the right tube a twist of 360° caused no strangulation, on the left a twist of only 180° caused very extensive interference with circulation. The uncoiled pedicle proved to be some two inches long and was much thickened by exudate, and at the point of torsion was distinctly necrotic in patches and very friable. The tubal wall was dark and much ecchymosed and the tube contained about an ounce of pus much discolored with blood.

Thus the patient presented on the right a hydrosalpinx with complete torsion, but no strangulation, while on the left what was probably a hydrosalpinx originally had become by partial torsion a hematosalpinx with subsequent infection. The ovary was not involved on this side either, and as there was still some circulation in the walls of the tube, having in mind the patient's desire not to sacrifice all chance of maternity, I removed only the outer portion of the tube and made a new ostium in it ("stomatoplasty") and anchored the stump in such a position that torsion could not recur. Recovery was uneventful and permanent.

This case is not exactly typical of torsion of the tube in that there was present on one side a quite severe strangulation, with practically no symptoms. It also illustrates on the other side the rarest form of torsion, that without strangulation, a condition of which I have been able to find only three other cases reported, that of Legueu and two of Poirier. While it is fairly common to find an ovarian tumor that has undergone several revolutions without interference with its blood supply, the relative shortness of its pedicle makes that happy result far less apt to occur in the case of the tube. While a comparatively rare accident, torsion of the tube doubtless occurs much more frequently than the few cases reported would lead us to infer. Rejecting numerous cases included by previous writers on the subject in which the tube was twisted merely as part of the pedicle of an ovarian tumor that had undergone torsion, I have been able to get more or less complete accounts of 62 cases. But as 5 of these are reported by one man and 4 by another, while three others report 3 apiece and two others 2 apiece, it seems fair to assume that closer observation would have shown many more cases.

Bland Sutton first called attention to the condition in 1890, so that the 62 cases noticed since then prove it to be a complication of real importance. Apparently the case of Dr. E. L. Pierson of Salem, which I mentioned in a paper read before this Society in 1896 on the "Axial Rotation of Ovarian Tumors," was the eighth case reported.

As I have said, torsion without strangulation is excessively rare. When it does take place, the symptoms are, as a rule, very alarming and are those of any acute internal arrest of circulation, sudden pain, almost always nausea and vomiting, faintness, complete arrest of bowels and often paralysis of bladder, combined with local tender-

ness and increase of the size of the tumor from venous congestion. But there is so little distinctive about this picture that in the 37 cases in which the diagnosis before operation is given, in only one is the claim made that the true condition was recognized, by Racoviceano-Pitesti in the case reported by Dona of Bucharest, although Cathelin considered its possibility in his case. In these 41 cases the supposed diagnoses were salpingitis, 12; twisted ovarian tumor, 10; appendicitis, 7; cyst of ovary, 3; internal strangulation, 2; hydrosalpinx, 3; intraligamentous cyst, 2; twisted ovary or tube, 1; twisted tube, 1.

The correct diagnosis can probably be made only when it is known that a hydrosalpinx has been present previous to the advent of acute symptoms and that that hydrosalpinx has undergone a rapid increase in size, especially if a previously pelvic tube has become abdominal. Warneck has mentioned metrorrhagia as being an important symptom, tending to be intermittent according to Pozzi. I find it present in seven cases. On the other hand, metrorrhagia is so constantly found under all varieties of lesions of the appendages, that its presence can have but little diagnostic value, and, furthermore, in these seven cases there was a uterine polyp in one and malignant disease in two others—conditions under which it might be expected anyway. Warneck also speaks of feeling the twisted pedicle by the vagina in one case. This seems a refinement of tactile sense that but few of us can aspire to. If made at all, the diagnosis must be based upon the sudden pain in a patient known to have tubal trouble, with the other symptoms mentioned. The fact that the vomiting does not become fecal would exclude volvulus, and the lack of muscular spasm and fever would render an appendicitis improbable, although in several cases the maximum pain was directly at McBurney's point, noticeably in Pierson's. So, too, when an appendix becomes adherent to a twisted tube and secondary inflammation of the appendix occurs, there would be little chance of a correct diagnosis (cases of Hartmann and Villar). In the fourth case of Pozzi and that of Martin, where a tube containing a fetus underwent torsion and ruptured as a result, of course the diagnosis of the torsion was impossible, while in tubes that have become twisted without strangulation, the diagnosis of the twist is, of course, equally not to be made.

As most of these cases are hemato- or hydrosalpinx rather than pyosalpinx, and therefore are not surrounded by masses of exudate, we should expect to find a distinctly elastic and more or less freely movable tumor. As, unfortunately, they are apt to lie high in the pelvis, or in fact be abdominal, the chance of confusing them with ovarian cysts is a great one. In 37 cases that mistake was made 14 times.

As to the causation of torsion, the various theories that have been suggested are as yet only theories. In a few cases the sudden stabbing pain has followed muscular exertion of one kind or another, but in the majority of them

nothing of the kind is alleged. Certain conditions, however, favor a torsion. The tubal tumor must be situated in the distal portion of the tube, and it must be unadherent, — therefore in all probability a hydrosalpinx, — and it will generally have a long and comparatively thin pedicle. I have mentioned that in my case the pedicle was more than six inches long and smaller than the little finger. In only one case, that of Clado, were as many as three turns observed with a short, thick pedicle. As he observes, "There is a tendency of the inflamed tube to increase in its long axis, which involves lengthening of the mesosalpinx in the part corresponding with its implantation on the tube, while the parietal part does not grow. Therefore the tube is now dependent on a fan-shaped ligament, a condition favorable for torsion." In Pozzi's first case, three-fourths of a turn was present in a very short pedicle.

For torsion to occur, the tubal tumor must be fairly high in the pelvis. It is also striking that the presence of a pelvic tumor favors torsion of the tube. In the 60 cases under consideration, the torsion was associated with myoma in 4, with pregnancy in 3 and with an extra-uterine pregnancy on the other side in 3, while in a number difficult to determine, the other tube was more or less enlarged with serum or pus. The rather large number of associated pregnancies is striking, as *a priori* one might have expected such cases of tubal disease to be sterile. In the 3 cases with ruptured extra-uterine pregnancy on the other side, it may have been that the torsion was caused by superlying clots, though in one of them the observer thought the rupture was caused by the torsion. In Mellroy's case, the torsion was apparently caused by labor. In the case reported by Dona, it is possible that the twist was caused by an abscess of the ovary rupturing into the tube and so suddenly increasing its volume. In one of Pozzi's cases there was a torsion of the left tube ten days after an operation for torsion of the right, which, by the way, was diagnosed as appendicitis. This Pozzi regarded as possibly caused by the increased tension resulting from the intense congestion of the pelvic organs following the first operation. This, however, does not explain why the right tube got twisted. As to the general question of causation, it is not difficult to understand that a more or less pear-shaped tumor, with one end heavier than the other, balanced in unstable equilibrium in the center of the pelvis, should be peculiarly liable to roll one way or the other and so undergo torsion. The only wonder is that more tubes do not become twisted!

It does not appear that Küstner's law of direction of torsion applies as closely to the tube as to the ovary. It will be remembered that according to this law there is an innate tendency for tumors of the right ovary to rotate outwards — to the right and of left ovaries to rotate outwards — to the left. While in the case of the tube there seems to be in many observers' minds a vagueness as to what a right and a left rotation means, as

nearly as I can make out, 19 right tubes rotated to the right 8 times and to the left 11, while 14 left tubes rotated an equal number of times each way. Instead of speaking of right or left rotations or turning, in accordance with or contrary to the hands of a watch, I think it would be much wiser to adopt the suggestion of Cathelin and speak of "antetorsion" and "retrotorsion," regarding always what was originally the top of the tumor as the starting point. Apparently the larger the tube the greater the probability that it will follow Küstner's law, for if large it will be an abdominal rather than a strictly pelvic tumor. One might expect to find that torsion would be favored by irregularities of surface, but as a matter of fact most of these tubes, while tending to be ovoid or pear-shaped, are remarkably smooth and symmetrical in outline. Busquet holds that the mechanism of rotation is much influenced by the position of the uterus. If, according to him, the uterus is anteflexed, the tube tends to roll backwards, and if retroflexed, the tube goes forwards. While this law probably holds good in the case of small tubes, it is to be questioned whether it would do so in the case of larger ones, and when the uterus is in normal axis, as in my case, some other explanation must be sought.

The number of turns may vary considerably, 4 turn to 5½ in the cases considered, with an average of 1½ in 41 cases. As in a number of cases repeated acute symptoms, "*crises à répétition*" of Leguen, have been associated with the same number of turns as acute attacks, it is evident that an adhesive peritonitis does not always follow strangulation unless we suppose that the adhesions that followed each torsion subsequently disappeared before the next twist. It is noteworthy that in most of these cases of repeated attacks the adhesions are spoken of as recent or easily separated. Adhesions of some degree almost always follow a torsion if strangulation results. Thus in 22 cases of hemato- and pyo-salpinx they were absent in only 2, and in one of these operation was before adhesions had had a chance to form (Gosset).

The number of turns does not appear to have any great influence on the degree of strangulation, which depends more on the length and size of the pedicle. Thus in 8 cases the tube was wholly or almost entirely separated from its pedicle, with an average of 1½ turns, while in 4 cases, in which no strangulation took place the average turns were 1½. As a rule the cases without strangulation had long pedicles. In my case the strangulated tube had a pedicle about two inches long, while the unstrangulated tube had a pedicle of at least six inches.

The seat of torsion was 30 times on the right — compared with only 19 on the left, while it was bilateral in 4. This tendency of the right tube to become twisted rather than the left is rather hard to explain, as left tubes are certainly more apt to become inflamed than are the ones on the right. It may, perhaps, be due to the anatomically greater play of the right mesosalpinx.

The tendency is unfortunate, owing to the probability of confusion with appendicitis.

The ovary is given as involved in 18 cases and not in 22. Apparently the symptoms were more severe when it was involved than when it escaped, as was natural. The immediate and definite result of strangulation of a tube is an effusion of blood into its cavity, combined with extravasations into its walls, adhesions to surrounding parts and very probable subsequent infection from the intestine. Thus while the 62 cases under consideration are given as: Hematosalpinx, 33; hydrosalpinx, 13; pyosalpinx, 11; extra-uterine pregnancy, 2; carcinoma, 1; sarcoma, 1; cyst of tubal wall, 1 (Stoltz), an analysis of the 13 cases called hydrosalpinx shows that in 4 there was no strangulation, while in several others there was more or less extravasation into the tubal wall, and in 2 the operation took place before there was time for a change from hydro- to hemato-salpinx. Practically, then, in all cases where strangulation occurs, a hematosalpinx will be found, and in fact it is highly probable that many of the cases carelessly regarded as extra-uterine pregnancies because a tube was found filled with blood, were in reality cases of strangulation by torsion.

The only treatment of this accident is naturally immediate operation. In the 62 cases under consideration there were only 2 deaths, that of Warneck (carcinoma) from ileus fourteen days after operation and that of Poirier (hematosalpinx) in forty-eight hours, from unknown cause.

THE OPEN-AIR TREATMENT OF TUBERCULOSIS.*

BY WALTER A. GRIFFIN, M.D.,
 Resident Physician, Sharon Sanatorium, Sharon, Mass.

THE treatment of pulmonary tuberculosis to-day means, in a general way, the same thing in the minds of everybody, — out of doors, fresh air, milk and eggs. These things have been so thoroughly preached by the medical profession that laymen know the general methods as well as we who preach. All drugs have been tried in vain. Specifics have had their day and have been discarded. Even climates have been relegated to the second or third place, since the experiment of institutions like that at Sharon have proved that sanatoria near at hand will give such excellent results. Not that the favorable influence of climate is to be entirely counted out, especially in selected cases, but the larger fact has been learned that with or without the advantage of a change of climate, the hygienic mode of living, so aptly called "elaborated common sense," is absolutely necessary in every place. The present day specifics, which are, for the most part, bacteriological in character, are still in the experimental stage. Whether they will stand the test or be forgotten with the rest of the "cures," time alone will tell. There is a large field for research at present and many problems are occupying the minds of men interested in tuberculosis, both in this country and abroad. Some reports are already at hand. Tuberculin has been tried and it is found to be of value in certain cases, but not in all, while the different sera, of which we are hearing so much at present, are as yet praised most loudly by those who have a money interest in their sale; therefore the results are not to be taken without some hesitation, although some of the reports are certainly striking. Doubtless, in good time, some therapy will be brought forward that will be accepted by every one as vaccination and diphtheria antitoxin are now accepted. I doubt, however, if there ever comes a time when any drug or any toxin or antitoxin will take the place of hygienic living. And it is because the details of this life are so important that it is well to go over them again, even at the risk of appearing wearisome.

The three essentials of the present day treatment of tuberculosis are fresh air, good food and carefully regulated exertion. It matters but little how these things are obtained, so long as the result is good. A patient may be treated on a house top, or in a tent, or in a shack in the back yard, or he may be the inmate of a well appointed sanatorium. If the air is fresh and pure, the possibilities are as good in one place as another. It certainly is an advantage if the patient is in

* Read before the Providence Medical Association, Dec. 4, 1905.

an environment where the air is dry, the soil porous, the site somewhat elevated above sea level and the temperature equable, but surprisingly good results can be obtained in decidedly poor environment, such as is found in large cities or near the coast. Pratt has experimented this last summer with some twenty-five patients in the heart of the city of Boston, and his report is certainly striking. The patients were among the poorest classes and could not go away. They slept at night in tents on the house tops or in back yards, and spent all their days out of doors. They had all there was of a not over good quality of air, and the result shows that even the poorest person, provided he can spend the time to get well, need not give up hope.

In making the patient take the fresh-air treatment, there are one or two points that are especially noteworthy. One is that the nearer the treatment is kept up twenty-four hours out of the day, the better. It is not sufficient that the patient spend his days out of doors and sleep at night with the windows closed. Nor should a patient work by day if it can by any means be avoided, and take the air only by night. It is impossible to give an overdose of fresh air, and the ideal arrangement allows only the sky for a roof at all times except in time of storm, and then only so much shelter as is necessary to keep out the wet. The devices for shelters are legion, and they fulfill the object for which they are constructed with more or less merit. Other things being equal, the simplest device is usually the best. Treatment can be fully as well, if not better, carried out in the lean-tos that have been devised by Dr. King of Loomis Sanatorium, or the shacks of Dr. Millet of Brockton, as in the most costly building.

Another point to be noted is that cold weather puts no hindrance to staying out, provided there is plenty of covering over the body, so that it does not feel chilled at any time. All consideration of personal appearance has to be put in abeyance, for rarely can one be comfortable out of doors in winter and look anything but bundled up. It is the physician's business to insist that the clothing be warm enough. The fact that the patient has always worn the same weight underclothes summer and winter is no argument, for cold will creep in mercilessly after sitting out for a few hours with the mercury at zero, unless there is plenty of woolen next the body. I have had to advise some to wear more than one suit of underclothing at a time and two or three pairs of stockings. The feet must be encased in heavy shoes and overshoes, or, still better, in old-fashioned felt shoes. At night the bed should be made up with a heavy blanket over the mattress, for much cold will otherwise come from below. The patient will also find that it is a great comfort to have a blanket laid loosely between the sheets, so that the body may be rolled in it. Even a sleeping bag may be employed, and the use of a night cap is not to be scorned, while, of course, hot water-bottles are of great value night and day. With these precau-

tions, it is rare that any great discomfort is experienced, and usually the life is enjoyed.

As regards feeding, I am sure that the final word has not been said, and possibly it never can be said. Patients differ so much, one from another, in their power to take and assimilate food that no fixed rules can be laid down. In some places it is still the custom to force the patient to take enormous amounts of food. In consequence, the gain in weight is usually great; but one cannot help feeling that the stomach is too frequently upset by this method, and in the end the gain in health no more than when the digestion is less heavily taxed. Patients are always expected to force themselves to a certain extent; the meals are always larger than those to which they have been accustomed. But with this moderate forcing the gain in weight and strength is, on the whole, as satisfactory as under the first course mentioned, while the dangers of crowding the patient are obviated. At Sharon we give food seven times a day. At seven in the morning and at nine at night a glass of milk is given out. In the middle of the forenoon and middle of the afternoon there are lunches of milk and one raw egg. These are supplemental to the three regular meals, all of which include meat of some kind. This dietary has to be modified in certain cases, for there are some that cannot take milk and eggs without much difficulty, and there are others who have gained so much that it seems best to omit the lunches altogether, directing the attention to making the tissues harder rather than to putting on more fat. In some institutions the caloric value of the food ingested is taken as the guide to determine the consistency of the diet. Such observations are of great value and will help in the future to make the feeding of tubercular patients more easy. Goodbody, Bardswell and Chapman conclude, from observing six patients, that the diet which gave the best results consisted of 120 gm. proteid, 110 gm. fat, 300 gm. carbohydrates.¹

This table is noteworthy on account of the large amount of fat that it contains, and differs especially in this respect from what is usually taken as the caloric needs of an ordinary healthy man. For a long time it has been known that consumptives can take fat more readily than normal individuals. Many make great point of this, giving much bacon and other fatty meats, butter, cod liver oil and olive oil. The reaction against giving cod liver oil has begun. Possibly the wisdom of giving the other fats will be called in question as time goes on. At Sharon there has never been any especial point made of fat, and still the gains have been satisfactory in most cases.

The amount of food in the list quoted is far below what is ordinarily thought necessary, although it is in excess of what patients can take solely to their own desires. It has been proved, however, that with a moderate degree of restriction not only can larger amounts of food be taken than the appetite desires, but a better quality of

¹ Med. Clin., 1900, 1, 100.

of the nitrogen and fat is absorbed than with a small diet. The object to be gained is a moderate increase of body weight over what would be normal for the individual with whom we are dealing, and when that object has been gained, it is well to cut down on the amount of food, for it is certain that patients can at times gain much flesh and still run down hill. Personally, I think that gains of one or two pounds a week are as much as could be desired, although we hear of patients who gain six and seven pounds.

The giving of eggs has doubtless been overdone. Some patients take so many that they loathe the sight of more. Three or four a day are a goodly quantity, and if the number is not increased beyond this, there is usually no difficulty in giving them for a long time. As for milk (for milk and eggs go hand in hand in the treatment), it is the most important single article of food and hardly to be dispensed with. From one to two quarts a day are the common thing to give, and with a careful adjustment of the amount taken the weight can frequently be made less or more at will. It is our routine practice to give each day about three pints of milk and two eggs to a patient.

Regulation of the amount of exertion is very important, and while it is generally better understood than formerly, there are still patients who are injured by being allowed to do too much. The majority of phthisical patients feel so well that it is hard to keep them within bounds. Even patients with temperature are not sick enough in their own opinion to stay in bed, and after they have so far gained in strength that they may be allowed to go about somewhat, it is even harder for the physician to hold them back. Nevertheless it is true that a slight indiscretion in the amount of exercise will at times be the turning point and send an otherwise favorable case down hill. I have to confess that I have on two or three occasions allowed and even been the witness of over-exertion in cases that have from that moment grown worse, where before there seemed to be at least a fighting show for the patients. Such experiences make one over-cautious, it may be, and still it is well to remember that few are injured by restraint.

As a general rule it may be said that when a patient presents fever he should be put to bed and kept there till the fever is abated. This may take weeks and be irksome to both patient and physician. But there is no reason why the treatment should not be somewhat like that of a typhoid convalescent who does not leave the bed till the temperature has been normal for at least a week. In some cases it is true that patients will not do well till they are allowed about, but for a routine measure, rest in bed is invaluable. We have had patients with advanced signs in the chest and with a temperature of over 102 at entrance. And we have kept them in bed for over two months, letting them see visitors for only a few minutes at infrequent intervals, and we have sent such cases out with the disease arrested. To be sure there have

been others that have not responded to this regimen, but it is rare that a case will do better by any other means if the condition is such as to warrant trying the rest cure.

When the patient is convalescent, the question of the kind and amount of exertion comes up. Walking is the most easily regulated and for most cases it is the best kind of exercise, until the disease is well on toward arrest. These walks should be prescribed as carefully as medicine, and the direction of the walk should be indicated, so that there may be no undue strain in getting home. In a general way, it may be said that two short walks are better than one long one if there is any tendency to weariness. As Brehmer said: "A healthy man sits down because he is tired; the consumptive should sit down so as not to become tired." When the patient has gained in strength to a large degree, the amount of exercise can be increased and the kind varied. Until the disease has been cured, however, it is unwise to advise the more violent sports such as tennis or rowing. Temperance must be shown even in the most simple forms of exercise. Patients have injured themselves by too much sewing or knitting or basket making, usually because they keep too steadily at it without laying the work down. For all patients it is well to prescribe a period of rest each day for at least two hours. At Sharon this is taken at one time in the afternoon. Occasionally it is necessary to supplement this with a rest before the noonday and evening meals, for the digestion is aided in certain cases by this means.

It is still a moot question whether pulmonary gymnastics shall be advised or not. Doubtless, where there is rapidly advancing disease, it is not well to prescribe deep breathing, especially if there is a pleurisy. Indeed, nature gives us the cue in many cases and by pain limits the respiration. In other cases, however, there can be no objection to moderately deep breathing, for by it the air of the lungs is better aerated, and certainly we cannot expect to get rid of diseased tissue in the presence of poor blood. It has been recently proven, also, that the secretion of the bronchial tubes is gotten rid of not so much by the action of the ciliated epithelium as by the pump-like action of the bronchial muscles.² This action closes the bronchioles during expiration and forces out any secretion that may be present. By moderately deep breathing, therefore, this pump-like action would be favored, and thus sputa would be more easily raised. Be this as it may, we have always advised deep breathing except, as stated, in rapidly advancing cases and in those with pleurisy, and we have not only never seen ill results follow, but the patients have gained with the practice. They are advised to take long breaths at least three times a day and oftener if they can remember to do so.

Carswell wrote in 1836: "Pathological anatomy has never afforded stronger evidence of the curability of a disease than in the case of phthi-

²Ingals: Jour. Am. Med. Assn., Oct. 28, 1905.

sis," and we all know that the majority of cases will get well if taken in an incipient stage, and if the points in treatment as above stated are carried out. This necessitates close supervision, for every particular point must be gone over many times, and certain details have to be modified from time to time to suit individual needs. This need of supervision is still frequently not made clear, and even to-day we hear of patients who are sent away with the general direction to live out of doors and take milk and eggs. Such advice is never to the best interest of the patient and frequently is disastrous to the doctor as well. Solly has shown that of patients coming to Colorado, the mortality is much less among those under supervision than among those who consult a physician only when they think it necessary. This is natural, since with tuberculosis it is so frequently needful to change certain details of the treatment for particular patients and at different times for the same patient. Doubtless it is far and away to the patient's interest to spend a time at some properly conducted sanatorium, at least in the beginning. Here he can learn all the necessary details of the life as it would be impossible for him to do elsewhere, even with good medical attention and counsel. Manifestly this cannot be in the majority of cases, and it is usually the case that needs it most that can get away least easily. Reliance must then be given to such shifts as the doctor and patient can agree upon, the former always remembering that the earlier he makes the diagnosis and brings the patient under treatment the better, and the latter realizing that he must not try to work alone, but must rely on his medical adviser in all things.

THE SUCCESSFUL TREATMENT OF TUBERCULOSIS

BY ALBERT E. RIVERS, M.D., BOSTON

Surgeon, Rhinologist and Laryngologist to Mt. Sinai Hospital, Medical Examiner for State Mutual Life Insurance Company of Massachusetts, Fellow of Massachusetts Medical Society, Member of American Medical Association, etc.

FIVE years ago the writer was called upon to treat a case of pulmonary tuberculosis in a far advanced stage. The patient had been treated at the Rutland Sanatorium without success and had been in Asheville, N. C., with a like result. It was at this time that I began to read with absorbing interest the reports of Dr. John Russell of the New York post-graduate dispensary. My interest was awakened to the extent of proposing to this patient a trial of the treatment as outlined in this paper and the experience then gained made me a convert to the method.

The theory upon which the originator of this method bases his treatment is that pulmonary tuberculosis is the result primarily of malnutrition. Further that the malnutrition which favors the growth and development of tubercle bacilli differs from other forms of malnutrition, namely, scurvy and rickets. The malnutrition of scurvy differs from that of rickets and both are produced by a deficiency of suitable food.

Malnutrition is defined as a condition of starvation, either partial or complete. All physiologists teach that to maintain proper nutrition, it is necessary to partake of a diet composed of proteins, carbohydrates, fats and salts in certain proportions; consequently, if the necessary proportion of any one of these essential elements of food stuffs is not maintained, nutrition suffers, and the degree must vary with the variation in the supply of an essential element. The form of malnutrition is determined by the definite deficient element. As yet we do not know the element lacking in scurvy, but it is well known what brilliant results follow the administration of certain foods.

Beside an insufficient supply of suitable food, malnutrition depends as surely upon defective absorption. Now to the careful observer of tubercular symptoms one of the commonest is the great distaste, if not entire repugnance for, fat foods. Patients almost without exception cut the fat away from their meats. This distaste arises from the inability to digest fat, and Russell believes, and I am now prepared to agree with him, that the malnutrition which renders the tissues favorable to the growth of the tubercle bacilli is produced by a deficient absorption of fat and that the successful administration of fat will correct this form of malnutrition. The conditions being no longer favorable the bacilli will not thrive and the disease is relieved.

Now and then there is a patient who, although to all outward appearances is well nourished and robust, will suddenly develop tuberculosis. This can be explained by nature's power of compensation, for both carbohydrates and proteins may be transformed into fat, and in this way a deficiency in fat is compensated for; but either compensatory fat is wanting in some essential quality, or else its manufacture weakens nutritive changes at other points.

Now, as has been said, the cure depends upon the successful administration of fats, and to accomplish this several things have been found necessary; namely, that a large part of the fat given shall be previously rendered absorbable or pre-digested, that a large quantity be given daily, and that there be a great variety of fat in the diet. Russell has found by experimenting that the greater the variety in the fats ingested, the greater the opportunity presented to the body in the process of selecting its necessary proportion of constituents, and the emulsion of mixed fats which bears his name contains beef-fat, coconut, peanut and olive oils and a small quantity of clove oil. The emulsifying favors the absorption, and for the sake of quantity and variety, raw eggs and milk are added to the diet. During the first week of treatment the emulsion alone is given, beginning with one-half ounce twice a day, increasing a half-ounce on each dose every three days until two ounces are administered twice a day. It is taken from one and one-half to two hours after the morning and evening meals. By this time the absorbents are accustomed to taking up fat and the patient is instructed to

take immediately after each meal one raw egg beaten in a glass of milk, and at the end of every three days add one more egg after each meal until four eggs are taken three times a day; then one egg additional is given at bed-time and this dose increased by one, until four eggs are taken four times a day. The next increase is to add one egg to any of the two meals thought most desirable. This last increase makes the total eighteen eggs a day. As the eggs increase the amount of milk is decreased, but never less than four ounces is used, and a bowl is employed instead of a glass. With a patient on this large amount of food a frequent unloading of the bowel is necessary, and it is here that the physician must have the courage of his convictions. He must explain and see to it that the patient understands that no matter how many times a day there is a movement of the bowels, if there is nausea, vomiting, abdominal pain or distress, or diarrhoea, that these conditions call for castor oil. It is necessary for some patients to take it in full doses every day; others require it only twice a week. On the days that castor oil is not taken, a pill such as the cascara or compound rhubarb pill is given. There are some patients who cannot take milk and eggs without nausea and vomiting, and who are not relieved by cathartics. For such, a mixture of sodium phosphate and sodium carbonate, 2 gr. to the teaspoonful of water, is given. From one to three teaspoonfuls is added to each glassful of the egg mixture. By these methods I have yet to find the patient who cannot be prevailed upon to take the requisite amount of food.

In well advanced cases and those which are running a high temperature, the patient should be confined to bed and given the emulsion and milk only. All other food is withdrawn. It is usually necessary to keep patients in bed from six to eight weeks. They are allowed to get up to use a commode conveniently placed to the bed. We begin by giving one quart of milk a day and gradually increasing the amount until our patient is taking five quarts daily. The emulsion is given as previously stated. At the end of about five weeks solid food is cautiously added, and the amount of milk diminished. When the patient has arrived at the point of taking his three meals a day, the forced feeding with the eggs is commenced. It has been found that in some patients after taking eggs for a long time, the condition of the lungs instead of improving commences to advance. The eggs are then withdrawn and the quantity of milk is increased, and cheese (I prefer the Swiss Gruyere) is added. The amount of animal flesh is also reduced to a minimum.

My personal experience is that most patients do well on the egg diet. Those patients who are lithemic do better on the milk and cheese. In all classes of cases one of the required conditions is, that the patient should remain out of doors constantly. The absorption of fat is greatly aided by an open-air life.

The illustrations show the manner in which I

require my patients to live. The tent has a wooden floor and end and costs twenty-five dollars. The shack has wooden floor, end and roof. The sides and other end are so curtained that they may be raised or lowered at will. The cost is thirty-five dollars.

Patients who live in the poorer districts can have the little piazza which is usually built on the back of tenement houses curtained with canvas and a bed placed there.

All patients are instructed as to the care of their sputum. Dishes are reserved for the patient's use and once every day those dishes are boiled. The patient's mouth is to be frequently rinsed in boric acid solution, and the face and

hands kept scrupulously clean. Of all the symptoms common to this disease but one is specially treated, and that one is hemorrhage. If a patient has a hemorrhage he is given ten grains of calcium chloride, in a teaspoonful of water, with each meal. This is continued for a long time, usually several months.

I believe this treatment to be applicable not only to uncomplicated pulmonary tuberculosis, but also to any form of tuberculosis, surgical as well as medical, and its more frequent employment will diminish the number of operations for tuberculosis. The following table will show that I have secured recoveries from pulmonary tuberculosis, tubercular peritonitis, periostitis, fistula and tubercular abscess. In these cases all physical signs have disappeared and there are no tubercle bacilli to be found in the sputum. They have been well for two years.

I have several more cases in whom there have been no physical signs and no bacilli for almost a year, and I have a number of cases now under treatment, all of whom are doing well.

I believe this plan of treatment to be very superior to climatic or sanitarium treatment. In sending a patient to another climate we ask him to make sacrifices which he is often unable to make. Moreover, we add the element of nostalgia, which is a very serious one in an already depressed patient, for, "Be it ever so humble

edge that he has guided many formerly hopelessly incurable patients to a healthy life, and thus done his share in eradicating the "great white plague"; that he has done by his fellow man as he would be done by. This is making use of his science in the spirit of *Christianity*, the only true *Christian Science*. Oh! How superior to that "bubble of the dream box," Eddyism.

Clinical Department.

A REVIEW OF FIVE CASES OF OVARIAN CYST WITH TWISTED PEDICLE.*

BY CHARLES M. GREEN, M.D., BOSTON.

Cysts of axial rotation of ovarian cysts, with twisting of the pedicle, are not as frequently observed as formerly, for the obvious reason that in these days such tumors are discovered and removed early, before the size of the cyst and other conditions that may produce rotation become operative. It may, therefore, be of interest briefly to review the following five cases which

| | No. | Sex | Occupation | Condition | Weight Beginning of Treatment 102 lbs. | Weight End of Treatment 150 lbs. |
|------|------|-------|----------------|---|---|---|
| Case | I | Man | Cigar maker | Pulmonary tuberculosis | | |
| " | II | Woman | None | Pulmonary tuberculosis Tubercular abscess of thigh Severe hemorrhages | 78 .. | 152 .. |
| " | III | Woman | None | Tubercular peritonitis | 75 .. | 118 .. |
| " | IV | Woman | School teacher | Pulmonary tuberculosis | 102 .. | 146 .. |
| " | V | Woman | Bookkeeper | Pulmonary tuberculosis | 111 .. | 138 .. |

| " | IX | Man | Clerk | Pulmonary tuberculosis | 108 .. | 128 .. |

there's no place like home." These same remarks are also true of a sanitarium, even if it be situated in the patient's home city. Furthermore, by treating patients at home we are practically instructing whole neighborhoods in the prevention and care of tuberculosis, and thus accomplishing much toward stamping out the disease in the only manner in which it will ever be done, viz.: by *education*. If philanthropists would donate their money to the establishment of a fund for the supplying of fresh eggs and pure milk to the tubercular poor, I believe very much more would be accomplished than by the establishment of sanatoria.

One important factor in the successful carrying out of this treatment is the personality of the physician. He must be kindly, sympathetic yet firm, and have the courage to maintain discipline. He should state to his patient that he is tubercular and explain to him fully the treatment and all its hardships. It is not enough to tell a patient in a general way to take milk and eggs and to keep in the open air. The doctor must enter upon the systematic treatment as above outlined, examine his patient frequently, avoid the administration of drugs, keep his patient encouraged, acknowledging no outcome but a successful one. If the physician will do this he will go to bed a tired man indeed, but happy in the satisfaction of a day well spent, and as the years pass by, he will be rewarded by the knowl-

edge that he has guided many formerly hopelessly incurable patients to a healthy life, and thus done his share in eradicating the "great white plague"; that he has done by his fellow man as he would be done by. This is making use of his science in the spirit of *Christianity*, the only true *Christian Science*. Oh! How superior to that "bubble of the dream box," Eddyism.

CASE I. L. S., aged thirty-eight, had had six full-term, normal labors, the last, five months prior to my seeing her. She sought advice on account of an abdominal tumor which she had first noticed a month or two after her last puerperium; during these three or four months she had observed that the tumor was growing larger. The menstrual periods were normal, and she complained of no symptoms except constipation. The uterus was found to be of normal size and in normal axis; in the right lower quadrant was a movable tumor, estimated to be five to six inches in diameter, and apparently a unilocular cyst of the right ovary.

On exposing the tumor at operation four days later, it was found to have made one complete axial rotation; the tube was enlarged and adherent over the cyst. There were no adhesions whatever, and the tumor was untwisted and removed without tapping. The convalescence was uneventful.

The cyst had a thick wall, measured 18 cm. in diameter, was of purple color, and contained thick dark brown fluid. Along one side was a pear-shaped thickening, 12 cm. long, made up of small cysts filled with rather soft, red tissue and clotted blood.

The case represents one of the simpler type of axial rotation. The twisting of the pedicle was obviously a gradual one, and therefore gave no

* Read before the Obstetrical Society of Boston, Dec. 26, 1905.

to no sudden or painful symptoms. While there was enough obstruction to circulation to cause passive congestion, moderate intracystic hemorrhage, and gradual enlargement of the tumor, there was not enough torsion to lead to strangulation, adhesions, or degenerative changes. As to the cause of the rotation in this case, we have present two of the factors mentioned as possible causes, namely, pregnancy, and the pear-shaped thickening along one side of the cyst, which may have been effective in producing disturbance of equilibrium. Incidentally it may be mentioned that the left ovary in this case contained a hemorrhagic cyst twice the size of a normal ovary; but the tumor was too small to have played any part in the rotation of the other ovary, and was not itself rotated. This left ovary was resected and with its tube left *in situ*.

CASE II. G. B., aged twenty-one, single, had had pain in the left iliac region periodically for the past eighteen months; menstruation had been regular, and bowels constipated. At the time of my first visit the pain was very severe; pulse 120, temperature 100° F. Examination revealed a fluctuant tumor as large as a five months' pregnant uterus, dipping into the anterior vaginal fornix, and extending from the left lower quadrant to the right of the median line. The cervix was small and central; but the uterine body was obscured by what was obviously a cyst of the left ovary in front of it.

On making the abdominal incision, it was found that the tumor was everywhere adherent to the parietal peritoneum, to omentum, and posteriorly to intestine. After freeing all but the intestinal adhesions, it was found advisable partially to empty the cyst in order to gain room to separate the intestinal adhesions by sight. One and one half-pints of bloody fluid were removed, the intestine freed, and the pedicle tied off. The pedicle was 2 cm. thick, and the number of twists was not definitely made out. The right ovary, enlarged to 4 cm. in diameter, was cystic, and with its tube was removed. The whole parietal peritoneum was reddened and oozed somewhat, but the abdomen was closed without drainage; the convalescence was normal. The cyst was dark purple in color, with dark red thickened walls, and measured 14 cm. in diameter; it contained coagulated, red, jelly-like material, and close by the twisted pedicle was a portion of ovary 3.5 cm. in length, dark red on section. Pathological diagnosis: hemorrhagic ovarian cyst.

In this case the axial rotation was obviously slow and gradual, and the torsion was much greater and the pathological changes more extensive than in Case I. The cyst wall must have derived a considerable nutrition from the extensive peritoneal adhesions, and it showed no degenerative changes. As to the cause of the rotation in this case, it is idle to speculate.

CASE III. C. M. R., aged twenty-five, married two years, but never pregnant, one week before my visit was suddenly seized with pain in the left lower quadrant; the pain was steady in character and had persisted since the invasion. She began to flow on the fourth day, less than three weeks after her last preceding period. The abdomen had grown larger within the past three days. There had been no vomiting or chills; pulse 110, temperature 101.2° F. The cervix was elevated low in the pelvis, the fundus was not

made out. The hypogastrium was filled with a rounded, symmetrical tumor rising to the umbilicus, flat on percussion, with tympany in the flanks, and with marked fluctuation wave, apparently a unilocular cyst of the left ovary.

Operation the following day revealed a dark, congested-looking tumor of the left ovary, with an axial rotation of 180°. The cyst was lightly adherent in many places, and firmly adherent over its posterior wall. It was at first hoped to deliver the tumor intact; but the twisted pedicle was not easily accessible owing to adhesions, and the cyst was therefore emptied of three pints of dark red fluid. The left broad ligament was then tied off, and as the adhesions were so dense as to endanger the bowel by forcible separation, the outer layer of the cyst was incised and the tumor enucleated. The left tube was not recognized. The right tube was the seat of a chronic process and evidently contained pus; the right ovary was cystic. This tube and ovary were removed without rupture, but some of the contents of the strangulated left cyst had been spilled into the pelvis, and there was considerable oozing from the separated adhesions; a gauze drain was therefore placed behind each broad ligament. The drains were started on the fourth day; the convalescence proceeded uneventfully, but was protracted to between seven and eight weeks by the infection of the lower half of the incision.

The right tube was 15 cm. in length, fluctuant, much dilated, tortuous, varying from 1 to 3 cm. in diameter, and filled with thick, bloody, purulent fluid containing pus cells and Gram staining bacilli in chains and clumps. The right ovary was practically made up of a thin, translucent cyst, 5 cm. in diameter, with a small amount of apparently normal ovarian tissue at one side. Whether this tubo-ovarian mass could have had any effective influence in causing the rotation of the larger cyst on the other side is a matter of speculation. The collapsed cyst of the left ovary was about 15 cm. in diameter, with a smooth, dark red outer surface and tough fibrous wall. The inner surface was lined with a greasy, grayish-white, friable pseudomembrane, in which the bacillus *proteus vulgaris* was found. Comparing these pathological conditions with the symptoms of the case, it seems obvious that this was an instance of rapid torsion, attended by acute enlargement of the cyst, the formation of adhesions and the rapid development of necrotic changes.

CASE IV. M. M., aged twenty-nine, had had, six years before, a normal, full-term labor, with afebrile convalescence. For the past six months she had had more or less pain low down on the right side, and had noticed a "swelling" in this region for the last few months; otherwise she had been in good health. The abdomen was enlarged by a tumor reaching to the umbilicus and extending somewhat more towards the right than to the left. The abdominal wall was so thick that no fluctuation wave could be made out; but the tumor did not feel as hard as a fibroid. The uterus was in normal axis and of normal depth. The abdomen was opened with a presumptive diagnosis of cyst of the right ovary, with a possibility of fibroid. A thick-walled cyst of the left ovary was found, adherent over its entire surface. The pedicle was much thickened and twisted, but I did not take the time to determine the number of rotations. The wall was so thick that it had to be incised before the trocar would enter; the contents were too thick to flow through the trocar, being of a mushy, hasty-pudding character and containing hair; they were therefore expressed and none allowed to escape into the abdomen. The cyst was drawn up as the posterior omental adhesions were separated, and the thick, twisted pedicle plaited off.

The left ovary was enlarged to 2½ inches and cystic, and was also removed. The pelvis was found to contain a considerable amount of material similar to the contents of the dermoid cyst, and at the time it was not apparent how it came there, in view of the fact that none was spilled when the cyst was emptied. The cavity was cleansed and drained and the abdomen closed. The patient made a good after recovery, but the pulse rose to 150 on the night after operation. There was some abdominal pain and moderate distention, relieved by enemata; the abdomen was always soft and not tender. The temperature had risen to 101° F. on the second day, with pulse at 160, and the patient died, apparently of shock, on the third day.

The cyst measured 22 by 18 cm.; color, reddish to gray. On one side a thick pedicle with injected vessels and thickened walls. The whole surface of the cyst was roughened by adhesions, and the wall was 0.4 to 1.5 cm. in thickness. The cavity was filled with soft, yellowish, fatty material, showing cholesterol crystals, and embedded in this material were several balls of very coarse, golden-yellow hair; no bone or teeth were found. On what was, at the time of operation, the posterior surface of this cyst was a smaller cyst containing a thick mass of inspissated material, but no hair. On the discovery of this subsidiary cyst, the presence of the material found free in the pelvis and above alluded to seemed to me adequately accounted for. It seemed evident that this smaller cyst had originally contained the material, and had ruptured long enough before operation for the opening to have closed before removal, or to have escaped detection afterwards. Pathological diagnosis: Dermoid cyst, with necrosis and inflammation.

All authorities agree that "dermoid cysts are more likely to undergo axial rotation than other ovarian tumors, and hence twisting of the pedicle is comparatively frequent in this variety of cystic growth."¹ Malcolm Storer, in his valuable paper on axial rotation read before this Society nine years ago,² states that "In about 83% of the 248 cases of torsion collected by him from various sources, the tumor was either polycystic, solid, or dermoid, that is, presumably, of more or less irregular outline and varying weight, the irregularities affording convenient points for the exercise of the force needed to produce rotation, and the varying weight tending to produce disturbance of equilibrium."

CASE V. E. P., aged fifty-nine, had had one normal labor and afebrile puerperium in 1872, and had been a widow for two years. She had not menstruated for fourteen years. She had had good general health, and said she had never had an attack similar to the present one. Three days before I saw her she had been seized with excruciating pain in the left lower quadrant; the pain lasted one day, and the second day thereafter the pain returned and became general over the whole abdomen. There were no chills, but she had vomited and had had slight fever. The abdomen was distended, tympanitic throughout, and tender. The vaginal vault was puckered, and in the apex was a small atrophic cervix. On the left was a mass reaching nearly to the umbilicus and slightly movable independently of the uterus. The following day there was slight jaundice, which disappeared the next day; pain disappeared in a few days. The diagnosis lay, to my mind, between cyst of the left ovary and pedun-

culated subserous fibroid, with a possibility of malignant growth; and operation was advised and accepted.

On opening the peritoneum a mass was found made up of adherent omentum, intestine, and a tumor proceeding from the left broad ligament; the tumor had the shape and appearance of an enormously distended Fallopian tube; the ovary could not be differentiated and was presumably involved in the tubal mass. The tumor had rotated once around from without inward, and the pedicle thus twisted was so small that it was tied off with a single ligature. The mass had a necrotic appearance, and it was obvious that degenerative changes must have taken place in consequence of the torsion of the pedicle. The right appendages were shrivelled and adherent, and were not disturbed. On the anterior surface of the atrophied uterus was a sessile, egg-shaped myoma, 4.5 by 3 cm., which was enucleated and the bed closed in with buried sutures. The abdomen was closed without drainage, and the patient made a rapid and uneventful convalescence.

Subsequent examination of the strangulated tumor showed that it consisted of tube and ovary; the ovary, cystic, the capsule-like wall, tense, dull, dark red in color, slightly roughened by exudation, with dimensions 10.5 by 8 cm.; the contents consisted of dark, reddish-brown fluid in which were numerous blood cells and cholesterol crystals. The tube measured 7.5 by 1.8 cm., with walls dark red and softened and lumen distended with dark blood.

On comparing the pathological conditions found with the patient's statement of her symptoms, it seems incredible that such extensive changes could have occurred in so short a time. It is a fair inference that the ovary was cystic and that the tube had been the seat of a chronic process for perhaps some time without having given rise to symptoms that led the patient to seek advice. And it is quite probable that the attack of excruciating pain occurred shortly after a sudden axial rotation of the tubo-ovarian mass, from whatsoever cause, with the consequent torsion of the pedicle, resulting in hemorrhage into the lumen of both tube and ovary, and in the inflammatory and necrotic changes noted.

A CASE OF ACUTE TORSION OF THE FALLOPIAN TUBE WITH HEMATOSALPINX.*

By W. L. BURGAGE, M.D., BOSTON.

THE patient, Mrs. H. M. W., twenty-six years of age, first came under observation Dec. 9, 1898. She was a blonde of average height, poorly nourished and anemic; five brothers and sisters enjoyed good health; her father died of cancer at sixty-nine years. She had been married two years and had not been pregnant, always considered herself delicate; menstruation painful for the first twenty-four hours, every twenty-eight days, five to six days' flow, three to four napkins. The catamenia had been irregular up to four years previously. She applied for treatment because of dysmenorrhea. The uterus was found to be ante-flexed, enlarged, the cavity measured 4.3 inches and retro-positioned, the right ovary was enlarged but not enlarged and not adherent; cavity of the uterus very sensitive to the sound and bleeding easily. I did a Dudley operation at this time, and careful examination under ether confirmed the diagnosis. The result was good and the patient was

¹ Ashton's Practice of Gynecology.

² Boston Medical and Surgical Journal, Nov. 5, 1896.

* Read before the Obstetrical Society of Boston, Jan. 23, 1899.

relieved. She was seen several times in the spring of 1899.

Nov. 20, 1899, Mrs. W. was seized with severe abdominal pain accompanied by intense nausea and was sent to St. Elizabeth's Hospital as a case of pelvic abscess on Nov. 26. I saw her on entrance and made out a tumor the size of a duck's egg in the region of the right tube. It was exquisitely sensitive to light pressure; there seemed to be no exudate about it or about the uterus; the temperature was under 100°; pulse good; face had an expression of great suffering.

Right Fallopian tube. Case of Mrs. H. M. W. Reduced about one third. Exact size—length 9.5 cm., with 4.5 cm. thickness 3.5 cm.; color, dark reddish brown; consistency, soft, fluctuating. a, Fimbriated end. b, Isthmus where twist of two turns to the right was situated.

An abdominal operation was performed on Nov. 28, and the hematosalpinx removed, and both ovaries, which were riddled with small cysts, were resected. The left tube was normal. There was no free blood in the peritoneal cavity; the omentum was thin and adherent to the pelvic brim and to the distended right tube; the tubal tumor, 9.5 cm. long and 4.5 cm. wide, was adherent to the bladder over a broad surface. There were two complete turns like the thread of a right-hand screw in the pedicle of the tube, which was formed at its isthmus by the tube and its mesosalpinx. The hematosalpinx was dark reddish brown in color, of a soft fluctuating consistency and measured 9.5 by 4.5 by 3.5 cm. When opened the pathologist found only blood clot but no chorionic villi. The patient made a normal convalescence.

In this case the torsion was undoubtedly acute. The patient had been seen a year previously, had been examined under ether and the diagnosis made at that time was unquestionably correct because of the thinness of the abdominal walls and the absence of fat in and about the pelvis. She had been examined a few months before the onset of the acute symptoms and the pelvic condition was as noted. During the time she was under observation,—from 1898 to 1902,—there were no symptoms or signs of pregnancy and no indications of gonorrhea. We are left at sea as to the cause of the hematosalpinx and of the torsion of the tube.

THE TRAINING OF NURSES. — According to the *Medical Record*, on March 29 a symposium on the training of nurses will be held at the New York Academy of Medicine, to discuss the question of the overtraining of nurses and to suggest remedies.

Medical Progress.

PROGRESS IN THORACIC DISEASES.

BY MARK W. RICHARDSON, M.D., BOSTON.

INTRATHORACIC DERMOID CYST.

SHAW and Williams¹ report a case of intra-thoracic dermoid cyst, together with a review of the previous literature on the subject. Only 35 cases are on record. The age at which patients first seek treatment may be anywhere from twenty to sixty. Generally they are first seen between the ages of twenty and thirty. The two sexes seem to be equally affected. The expectoration of hair occurred in 7 of the 35 cases. The cysts are most often seen in the upper part of the chest, and have their origin apparently in the mediastinum. They vary in size from that of a pigeon's egg to that of a child's head. A tendency to invade surrounding organs is common, and pulmonary involvement is followed not infrequently by hemoptysis. In the absence of hair in the sputum the diagnosis is very difficult. Surgical treatment alone offers any hope of relief.

The case seen by the writers was a woman, twenty-six years of age, who had had a cough for several years. There had been on several occasions hemoptysis, and the sputum had frequently contained hairs. For six months there had been wasting, dyspnea and night sweats. X-ray examination showed the position of the tumor to be in the right chest just below the clavicle. No tubercle bacilli could be found in the sputum. Patient was discharged from the hospital unrelieved.

BY WHAT ROUTE DO TUBERCLE BACILLI FROM THE MOUTH AND THROAT REACH THE LUNGS?

According to Beitzke² three different routes have been mentioned as possible: (1) Cervical glands, truncus lymphaticus, superior vena cava, heart, lungs; (2) ¹/₂ cervical glands, supraclavicular glands, top of pleura, lung; (3) cervical glands, bronchial glands, lung.

Beitzke showed by the injection of anatomical preparations that the cervical glands were never connected with the bronchial glands, and very rarely with the supraclavicular glands. Injection fluid, moreover, never reached the top of the pleura. Beitzke thinks that although infection in animals may, possibly, be produced by way of cervical glands, truncus lymphaticus, superior vena cava, heart, lung (route 1), in children, at any rate, the primary lesion is in the lung, and that the bacilli are inhaled. Whatever tuberculosis is found in the cervical glands is coincident, and bears no direct relation to the pulmonary condition.

To assist in the early diagnosis of pulmonary tuberculosis in those cases in which sputum is lacking Blume³ recommends the following procedure: An ordinary glass slide is placed in a small, specially made holder. This slide is held

¹ *Lancet*, 1905, Nov. 4.

² *Berl. Klin. Woch.*, July 3, 1905.

³ *Ibid.*, Aug. 21, 1905.

in front of the mouth, and the patient coughs upon it every morning for eight or ten days. In this way quite a collection of small sputum droplets are obtained, which, when dried and stained, not infrequently show tubercle bacilli.

ABORTIVE PNEUMONIA.

According to the literature which Bechtold¹ gives in full, abortive pneumonia with crisis within twenty-four hours is not so very rare. In Leube's clinic from 1887 to 1905 there were 1,057 cases of pneumonia among which were 10 which lasted only twenty-four hours. All these cases were characterized by sudden onset with chill and high fever, followed in twenty-four hours by profuse sweating and fall of temperature. Local pain was present in 8 cases, and pointed almost surely to the seat of the lesion. Physical signs were but slightly marked. In two cases there was no dullness whatever, and the diagnosis was made on the severe general disturbance and the auscultatory signs, rough breathing and crepitant râles. Twice there was bronchial breathing and twice pleural friction was heard. Bronchophony was present in four cases. A characteristic rusty sputum was seen once. Once the sputum contained bright blood. There was no report as to the bacteriology of the cases.

THE X-RAY DIAGNOSIS OF THORACIC ANEURISMS.

Baetjer² reports four years' experience at the Johns Hopkins Hospital with x-rays in the diagnosis of thoracic aneurism. This diagnosis was made 104 times. In 70% to 75% of the cases the diagnosis had already been made by other methods. The x-rays practically always confirmed the medical findings. In 20% to 25% of the cases the diagnosis was doubtful but in many instances, the subsequent course of the disease proved the x-ray diagnosis to be correct. In 5% of the cases the aneurism was found by accident, there being no physical signs. Eighteen per cent of the cases came to autopsy, and the x-ray findings were always confirmed. In view of such results the value of the x-rays in diagnosis of thoracic disease is apparent.

Meyer Westfeld³ reports a case in which extensive adhesive pericarditis with failing cardiac compensation was relieved by operation. The patient a young man of twenty-four had had two attacks of pneumonia with pleurisy. The chief physical signs were systolic retraction of the thorax at the cardiac apex and diastolic collapse of the veins of the neck. There was no paradoxical pulse. Probable involvement of the heart muscle was indicated by signs of passive congestion in lungs, liver, kidneys, peritoneum and lower extremities.

At the operation the fourth and fifth ribs were resected from sternum to the anterior axillary line, and the heart was freed from its adhesions. Recovery was slow but constant. Thirteen weeks after the operation the signs of passive

congestion had disappeared, and the patient felt able to take up light work.

Weinberger⁴ and Pesci⁵ give very favorable reports of digalen as a cardiac stimulant. The advantages of digalen over old digitalis preparations are: (1) Absence of irritating properties; drug can be given as well subcutaneously as by mouth; (2) more exact dosage is possible, the composition of the drug being always the same; (3) inasmuch as intravenous injections are very well borne, maximum stimulation can be obtained in emergency cases in a very short space of time. Drug should be given in daily doses of 2-3 cc, until there is distinct slowing of the pulse. It is then to be omitted. There has been no evidence of cumulative action.

OPIMUM IN HEART DISEASE.

Musser⁶ urges the more common use of opium in myocarditis, weak heart and dilated heart. The use of opium seems to be especially indicated in, (a) sudden failure of the myocardium; (b) to prevent or lessen the effect of angina pectoris; (c) in weak heart after exhausting disease, and after prolonged mental and physical pain without valvular or muscular lesion; (d) in failing compensation when patient is very nervous or irritable; (e) parenchymatous nephritis and in arteriosclerosis; (f) tachycardia of Graves' disease.

HEMORRHAGIC PLEURISY AS A COMPLICATION OF EXOPHTHALMIC GOITRE.

Breton⁷ states that hemorrhage is a not very uncommon event in exophthalmic goitre. It has been seen in nose, retina, brain, lung, stomach, intestine and uterus. Less common is hemorrhage into the pleura, and of this Breton reports a case. The patient was a woman of sixty-nine, who had had trouble with her thyroid from the age of puberty. An increase in size of the tumor had been noted after each of two pregnancies, and especially after the menopause. She was under observation for over a year. She was tapped several times on account of increasing dyspnea, and in practically all instances bloody fluid was removed. Temporary improvement followed. Thorough examination never revealed any pulmonary disease. She was treated at first with large doses of opium with temporary relief. Electrotherapy helped the tachycardia. The use of "hemato-ethyroidine" was followed by decrease in size of the tumor, and decrease in the pulse rate. The drug was then omitted but the symptoms returned and there were furthermore renewed signs of a pleural effusion. Resumption of the "hemato-ethyroidine" was followed by a retrogression of the symptoms, and the treatment has been continued up to the present time.

TOXIC AGENT IN TUBERCULOPNEUMONIA.

Bren⁸ contributes an interesting study of the action of the toxic agent in lobular pneumonia, and its bearing upon therapeutics. A full article

of the toxic agent causes stimulation of the central nervous system and increased activity of respiratory and circulatory mechanisms. Intense action of the toxic agent produces overstimulation, over-work, enfeeblement and exhaustion. There is also direct destructive action of the toxin upon the tissues themselves which causes them to break down prematurely. Death is due to (1) exhaustion of the respiratory center and (2) circulatory insufficiency with resulting accumulation of the toxic agent and cardiac exhaustion. As to therapeutics, in the absence of a specific antitoxin we must try to eliminate the toxin or to mitigate its harmful influences. Internal hydrotherapy is of great value. A large urinary out-put should be induced by the large ingestion of water, and also by the use of digitalis. Fever is to be met with external hydrotherapy. Pain may be relieved by the ice bag and analgesics; restlessness by external hydrotherapy, analgesics and narcotics. Respiratory and circulatory conditions are of especial importance. For the respiration heroin seems to be the ideal drug as it decreases and at the same time deepens the respiration. In rare instances, however, it may produce untoward cardiac symptoms. In such cases morphia may be substituted. Inhalation of oxygen is probably useless and may be harmful by increasing inflammatory process. As to circulatory sedatives, these are in general contra-indicated, except that nitrates may be of value during early periods of increased cardiac work. Alcohol is indicated in alcoholic cases. Circulatory stimulants are contra-indicated except members of the digitalis series. Strychnia, caffeine and cocaine are not to be used because they stimulate the respiratory center which is already overexcited.

Shively¹² gives some interesting statistics as to the incidence of tuberculosis in large families. The effect of repeated pregnancies in quick succession upon the health of the mother and her susceptibility to tuberculosis cannot but be bad, especially when combined with hard work, poor food and other debilitating conditions of life. The effect upon the children has not been so clear, though Brehmer claimed that the later children of large families were more apt to become tuberculous. Shively, however, as the result of observations upon 1,175 cases of tuberculosis in families containing from five to thirteen children concludes that there is no constant or uniform numerical progression from the first to the last child as there should be if a greater susceptibility to consumption really existed in the later children. On the contrary the distribution seems to be quite remarkable in its evenness.

Conklin¹³ reports a case of resuscitation by manipulation of the heart of a man apparently dead from shock. The heart had ceased to beat for at least two minutes and manipulation for forty or sixty seconds was necessary before heart action returned.

Leube¹⁴ calls attention to the presence of a venous pulse in cases of anemia and its value in the differential diagnosis of cardiac conditions. The venous pulsation, as seen in the jugular, is sometimes quite marked. Sometimes it is simply suggestive. In the latter case it can be increased by pressure upon the liver. It is to be explained by a relative insufficiency of the tricuspid valve caused by the anemia and is the analogue of the mitral insufficiency seen under similar conditions. The symptoms in both cases disappear with improved blood conditions. In some cases of anemia the venous pulse may be present and no other evidence of tricuspid insufficiency. In such cases we must assume that valvular leakage exists, but that it is not sufficiently pronounced to produce other symptoms. In determining whether a mitral insufficiency, in the presence of anemia, depends upon endocardial changes or upon an impoverished blood condition, the venous pulse may give considerable help, for in simple anemia the insufficiency of the mitral and tricuspid is coincident and not accompanied by other signs of impaired circulation. Where the leakage of the mitral rests upon endocardial changes, the involvement of the tricuspid follows only after a considerable interval of time and there is also evidence of other serious circulatory disturbance.

Reports of Societies.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

EIGHTEENTH ANNUAL MEETING, HELD IN LOUISVILLE, KY., DEC. 12, 13 AND 14, 1905.

THE Association met at the Seelbach Hotel, under the presidency of DR. LEWIS C. BOSHER, of Richmond, Va.

After the usual preliminaries, the reading of papers was begun.

SURGICAL REPAIR OF INJURED NERVES.

DR. J. SHELTON HORSLEY, of Richmond, Va., reviewed the work of recent investigators on the histological regeneration of nerves. He alluded to the views of Beth and others, who claim that regeneration of a peripheral nerve can take place without central connection. He classified the surgical methods of repair as follows: (1) Simple nerve suture, including all cases where the ends of the nerve are brought into direct contact and sutured, even when nerve stretching or resection of the long bone may be necessary. (2) Flap operations, which were usually unsatisfactory. (3) Nerve bridging. By this term was meant those cases in which a foreign substance was used to bridge over the defect between the ends of a divided nerve. This included not only transplantation of nerve tissue from lower animals, but also *suture à distance*. (4) Nerve implantation or anastomosis. Under this head were included those cases in which the ends of an injured nerve were implanted into a healthy nerve.

He reported a case falling under the last classification. The patient had suffered an injury as a result of which the upper part of the median nerve had been destroyed for two and a half inches and the musculo-

¹² New York Med. Jour., July 8, 1905.

¹³ *Ibid.*, Sept. 2, 1905.

¹⁴ Zeit. für Klin. Med., vol. lvii, p. 199.

spiral injured in the lower part of the arm with paralysis of all muscles in the hand and forearm except those supplied by the ulnar. Three months after this the median was implanted laterally into the ulnar. Fourteen months later both flexion and extension had returned to a marked degree. At that time the musculo-spiral was cut across and implanted laterally into the median. Ten months after the second operation sensation and motion of the hand and forearm had almost completely returned. In discussing several points connected with the case, Dr. Horsley concluded that the extensors must have been supplied through the anterior interosseous of the median, because flexion and extension improved simultaneously, and because extension was not interfered with at the second operation, when the musculo-spiral was completely divided.

DISCUSSION.

DR. CHARLES H. MAYO, of Rochester, Minn., said one question that interested him more especially was the difference in the ability of repair of a sensory nerve and a motor nerve, also combined sensory and motor nerves. For instance, about the head, where we had the purely motor and sensory nerves it was almost impossible to keep a sensory nerve from uniting itself. It would get out and grow for inches and repair itself; but a sensory nerve having peripheral impulses towards the center seemed to lack regeneration like a motor nerve in which the impulse came from the center out. He had taken out the infra-orbital, plugged the opening with silver, and had a case as many as seven years without return of sensation in that area, yet within a few months, after operating again, and removing the silver plug, the sensory nerve which had been lying dormant for this length of time, would get out, hunt up a partner, so to speak, and go to work. Take the motor nerve of the arm, where there were acute sensory and motor nerves, we would get more rapid regeneration because of the peripheral impulses, and as the sensory nerve of the arm was so much in excess over that of the leg, we would get earlier repair in the surgery of nerves of the arm than we would in the leg.

DR. HORSLEY, in closing the discussion, called attention to the point that his patient was of a low grade of intelligence, whose nervous system was not well developed, and the same law applied here as would apply to other similar cases, namely, the lower the type of organism, the more rapid and more active the repair.

FOREIGN BODIES IN THE ESOPHAGUS.

DR. STUART McGUIRE, of Richmond, Va., said that the diagnosis of foreign body in the esophagus was based on the history of the case, the external palpation of the neck, the passage of an esophageal bougie, and finally by the use of the x-ray. The character and location of the foreign body being determined, the practical question was how to remove it. If it was round or smooth, efforts should be made to extract it with forceps and probangs, or to make the patient eject it by swallowing masses of partially masticated food and then vomiting. If it be small, it might seem wise to endeavor to push it into the stomach. None of these expedients should be tried when the foreign body was pointed, sharp or angular. Under modern surgical technique, an open operation was the safest procedure. There were two means of approach, one by an external esophagotomy, the other by a gastrotomy, and the selection of the method would depend on the location of the impaction. If it was opposite the cricoid cartilage, an esophagotomy should be done,

if it was below the level of the supraclavicular notch, then gastrotomy should be performed.

As an illustration of the operation of esophagotomy and gastrotomy, he reported two cases. In one, the patient, aged ten, while playing with a glass stopper, put it in her mouth and swallowed it. It lodged in the esophagus opposite the cricoid cartilage and produced complete obstruction. The foreign body was removed by an external esophagotomy.

The second case, a baby, aged seven months, while being dressed, seized an open safety-pin and put it in its mouth. The mother, in her efforts to remove it, pushed it first into the fauces and then into the esophagus. The pin was removed in the case by a gastrotomy.

DISCUSSION.

DR. J. WESLEY LONG, of Greensboro, N. C., narrated the case of a forty-six-day-old infant who had swallowed an open safety-pin; the pin lodged in the esophagus opposite the two cricoid cartilages. A radiograph, however, showed that the point of the pin was below the arch of the aorta. It produced constriction of the esophagus where the left bronchus crosses it, and the pin was removed by an external esophagotomy without any shock. He thought there were some cases in which this operation was preferable to gastrotomy.

DR. W. S. GOLDSMITH, of Atlanta, Ga., mentioned the case of a patient who had swallowed the concave part of a dental plate, which lodged in the esophagus and was retained there for a period of four months. At the end of this time, patient was very much emaciated and weak. After locating the foreign body, efforts were made to extract it with forceps, but this could not be done. It then occurred to him to try Bull's method of attaching a series of sponges to a long silk ligature and using an esophageal bougie, passing it out through the mouth and leaving in position the series of sponges. After attaching the bougie, it was a simple matter by a few sweeping movements backward and forward to push the foreign body into the stomach and extract it through the gastrotomy opening. The foreign body was of such consistency that the x-ray was of no aid.

DR. H. A. ROYSTER, of Raleigh, N. C., reported the case of a child, two years of age, who, two weeks previously to his seeing the case, had swallowed the wheel of a tin toy wagon. The child was able to swallow liquids, but not solids. During this time it subsisted on milk and liquid food. He used a medium-sized shotted semi-elastic bougie for the purpose of an examination; this passed into the esophagus, met with some resistance, after which he was enabled to pass it further without obstruction apparently. After applying a mouth gag, he was enabled to extract the foreign body with an esophageal forceps. The foreign body lay transversely across the esophagus.

DR. J. SHERMAN HENSLY, of Richmond, Va., said if a foreign body could not be removed by ordinary means, no time should be lost in resorting to early operation. He reported the case of a child who had swallowed a camel from a grab bag. The child put it into its mouth, it was situated a little lower than the level of the larynx. He tried to extract it by several different methods, but was unsuccessful. He saw the child on the fourth day after it had swallowed the foreign body, did an esophagotomy, and removed it with comparative ease. The esophagus was injured and gangrenous. Septic symptoms developed, and the child died on the fourth day following the removal of the foreign body. He thought the child might have been saved by an earlier operation.

DR. CHARLES M. ROSSER, of Dallas, Tex., reported two cases of foreign bodies in the esophagus. In one, the foreign body, an ordinary pin, was located by the x-ray, but could not be removed by ordinary means. Two-thirds of the pin was buried, but with the aid of the fluoroscope the pin was caught by its head, and with forceps extracted.

In the other case, a child, a nickel was located within two or three inches of the cardiac end of the esophagus. Gastrostomy was performed, and the foreign body extracted. The child lived about six or eight hours, then died, apparently without shock.

DR. RUFUS B. HALL, of Cincinnati, Ohio, reported the case of a child of a physician, five months old, who swallowed a safety-pin an inch and a half long. It remained in the esophagus for a time, but at the end of twenty-four or thirty-six hours the symptoms caused by its presence disappeared. The child was able to take the breast and thrived well. An x-ray picture was taken which disclosed an open safety-pin in the pyloric end of the stomach. Parents declined an operation for its removal until unfavorable symptoms developed. Several x-ray pictures were taken; but the child did not develop any unfavorable symptoms referable to the presence of the safety-pin. When the child was twenty-six months old, it passed the pin by the natural route. The child is now seven years of age.

DR. W. D. HAGGARD, of Nashville, Tenn., related the case of a child, eighteen months old, who swallowed a pin the head of which was as large as a cherry-seed. The child developed cough, and the presumption was that the pin had lodged in a bronchus. An x-ray picture threw very little light in regard to the presence of the foreign body. The pin appeared to be in a bronchus, with its head down and to the left. The child had little or no pulmonary symptoms, to justify him in doing an operation. At the end of ten days another x-ray picture was taken, but the symptoms were so slight that operation was deferred. Four days later another radiograph was taken, which failed to locate the pin, and shortly after this the child passed the pin by the natural route.

DR. MCGUIRE, in closing the discussion, said no hard and fast rules could be laid down as to whether esophagotomy or gastrostomy should be done in a given case. Of the two operations he preferred to do gastrostomy. It seemed easier and the after-treatment was simple. If it was equally applicable, it was the method to be adopted.

GALLSTONES IN THE CYSTIC DUCT.

DR. L. H. DUNNING, of Indianapolis, Ind., presented a method which he had employed in one case which greatly facilitated the pressing backward into the gall bladder of a stone impacted in the cystic duct. In this case the gall-stone was lodged in the cystic duct in front of a small stricture. After making all the efforts he deemed prudent to press the stone backwards into the gall bladder without success, he then unsuccessfully attempted to dilate the stricture with the finger-tips and later with forceps. One of his assistants suggested that he thought they could better dilate with the forceps if they could see the stricture. The walls of the gall bladder were elastic. The liver had been turned upwards, so that the gall bladder was near the surface. The opening in the gall bladder through which he had been working was enlarged a little, and then the stone was steadied and held against the stricture by an assistant. The fundus of the gall bladder was pushed forward toward the strictured entrance into the cystic duct. They so far succeeded as to bring the opening in the wall of the gall bladder

directly opposite to the strictured opening. They then tried to introduce the forceps tips, but failed. Picking up a pair of probe-pointed scissors curved on the flap, the point was gently worked through the fistula and the scissors opened; this did not dilate the opening sufficiently, so the edge of the fistulous ring was snipped slightly in two or three places, when they were able to dilate the fistula, so as to permit the easy exit of the stone. The operation was completed in the usual way. A rubber tube was fastened in the gall bladder and that viscus anchored to the fascia. Before they had finished the operation a little bile had flowed into the gall bladder. Two or three ounces of bile were discharged from the tube daily; at first it was dark and thick, but gradually approached the normal color and consistency. The patient made an uneventful recovery, and had but little further pain or soreness in the gall bladder region.

He thought the procedure adopted in this case might be found of service in others. It was not applicable to cases in which the gall bladder could not be brought near the surface, or where the gall bladder was thickened by inflammatory deposits.

In the author's experience in operating upon ninety-three cases of gallstones, there were ten cases of stone in the cystic duct requiring considerable effort to dislodge them. In two of the cases early in his experience the stones were crushed and portions left behind, subsequently giving so much trouble that cholecystectomy was finally performed.

(To be continued.)

Recent Literature.

Culbreth's Materia Medica. A Manual of Materia Medica and Pharmacology for Students and Practitioners of Medicine and Pharmacy. Comprising all Organic and Inorganic Drugs which are and have been official in the United States Pharmacopoeia, together with important Allied Species and Useful Synthetics. By DAVID M. R. CULBRETH, Ph.G., M.D., Professor of Botany, Materia Medica and Pharmacology in the University of Maryland, Departments of Medicine, Pharmacy and Dentistry. Fourth edition. Revised to accord with the new United States Pharmacopoeia, eighth decennial revision. Octavo, 976 pages, 487 illustrations. Philadelphia and New York: Lea Brothers & Co. 1906.

This excellent book contains much valuable information, concerning the description and composition of drugs. Many drawings are included. It is comprehensive, well arranged and well indexed. In places the style loses in the author's effort to condense. It is, however, unhesitatingly recommended both for study and reference.

The physiological action of drugs is described. Organic drugs from the vegetable and animal kingdom, inorganic carbon compounds, non-pharmacopoeial organic carbon compounds and the use of the microscope in materia medica are all carefully covered. The appendix includes a discussion of the treatment and antidotes of poisons, prescription writing and table of weights, measures, doses, etc.

THE EPIDEMIC POSSIBILITIES OF UNRECOGNIZED OR UNREPORTED INFECTIOUS DISEASES.

THE importance of recognizing communicable diseases early in their course, to the end that measures for the protection of the community from the spread of infection may become operative without delay, is a matter in general so well understood that comment upon it in these columns might seem unnecessary. The facts set forth in a letter recently sent by the secretary of the Massachusetts State Board of Health to the health officials of the town of Medway, make it apparent, however, that it is possible for conditions to exist in some of our communities, even in so hygienically civilized a state as Massachusetts, which not only are highly prejudicial to the public health, but give evidence of a lack of medical skill, or a willingness to suppress the truth, of a deplorable and alarming.

It appears that during the last ten days of February, thirteen of the fifty odd persons of a factory boarding house in Medway were taken sick. All but one of these were young women who were lodgers at the house as well as boarders. The physician called to attend the first patient observed symptoms which he regarded as suggestive of typhoid fever. Upon being consulted, he was informed that his services were not longer desired, and that medical attendance for the lodgers would be rendered by the physician designated by the proprietor of the boarding house and by none other. At the end of a week six persons were sick. They were cared for in the boarding house by a female physician who diagnosed them as cases of grippe, her diagnosis

being confirmed by a practitioner of the same school, whom she called in from a neighboring town. The sixth, a young man, lived in a private house and came under the care of a physician who early regarded the case as probably one of typhoid fever, and who later so reported it.

On March 5, sixteen days after the first person was taken sick at the boarding house, information was received by the State Board of Health which led to an immediate investigation. Inquiry revealed the conditions already described together with the fact that seven more individuals had been taken sick, making in all thirteen, of whom only one, the young man above mentioned, was regarded as suffering from typhoid fever. It was learned that of the twelve young women two had been allowed to return to their homes in Maine, and two to go to relatives in Swampscott, that three others had been sent to hospitals in Milford; that one was in a private house in Medway, and that four remained at the boarding house. All of these twelve patients were regarded by the attending physician as cases of grippe; no recourse had been had to the serum test for typhoid fever, and no prophylactic measures were in operation. Of the two patients removed to the private hospital in Milford (conducted by the physician called in consultation), one was taken sick on Feb. 19, the other on Feb. 27. They were removed to the hospital, the one on March 3, the other on March 5. When seen by the representative of the State Board of Health on March 7, both were so sick that the nature of the disease was clearly apparent, and one of them died nine hours later. Autopsy in this case showed the characteristic lesions of typhoid fever. Blood from these patients, and from the four others in the boarding house, gave a most pronounced Widal reaction.

From the physician attending them, it was learned that the two persons who went to Swampscott were suffering from typhoid fever, and that in each case the blood gave a positive Widal reaction. It has been learned that three additional cases of the disease have occurred since March 5, making a total of sixteen, that six patients have been removed to the hospital from the boarding house, and that the latter is still

At the time of writing no information had as to the probable cause of the outbreak, and as to the probable cause of the outbreak, it was certainly not typhoid fever. Still, the case was so obviously suggestive of typhoid fever, that the contagion, the importance of which has been taken into consideration, is not our intention to

possible channels through which infection may have entered this boarding house, but rather to call attention to the serious consequences possible where the presence of typhoid fever remains unrecognized or concealed in a community, especially under circumstances highly favorable to its spread. All of the patients in this instance were operatives in a factory employing more than one hundred persons. Several of them persisted at their work long after they should have been in bed, alike for their own good and for the safety of others. The spread of typhoid fever is at times most insidious, although knowledge of the occurrence of the bacillus typhosus in the urine, it may be for many weeks after recovery from the disease, throws some light upon the origin of epidemics.

The Commonwealth provides, through the diagnosis laboratory of the State Board of Health, a most valuable aid to the physician in the early diagnosis of typhoid fever. There is no excuse for the practitioner who fails to make use of the Widal test, gratuitously performed, in any case where the clinical symptoms do not justify a diagnosis without it.

In the present instance there would seem to be very little by way of extenuating circumstance. We believe that it is inconsistent with the present standard of general medical intelligence to charge to the account of "grippe" a series of cases presenting as did these many of the symptoms of an acute infectious disease, without duly considering typhoid fever as a possibility, and without having recourse to so valuable an aid in diagnosis as the serum test. The physician is by no means infallible, but where the public health is in any degree involved, the public may rightly demand the exercise of intelligence and of the utmost carefulness.

More serious, however, than any exhibition of ignorance or carelessness, is the suggestion in this affair of an attempt to disguise the facts, and to withhold from the health officials and from the community at large the knowledge of the existence within it of a communicable disease. Such a practice as this, conceived, it may be, in comparative ignorance as to its portent, is a most serious menace to the public health, and is capable of working great harm to any community.

The publicity given to this incident should suffice to secure to the people of Medway immunity from any repetition of it, and ought to serve as a warning to all others never to trifle with a matter so intimately connected with the public safety as the control of infectious diseases.

THE REPORT OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS.

THE thirty-sixth annual report of the State Board of Health covers the work of the Board during the year 1904, and is a most interesting record of admirable work, to which we have been so long accustomed.

The death-rate for the year, 15.76, was the lowest for more than half a century, with a striking decrease in all the infectious diseases except tuberculosis and cerebrospinal meningitis.

Weekly mortality returns voluntarily sent to the Board for a population estimated at 2,135,416, or 68% of the population of the state, and the statistics required by statute for towns and cities of 5,000 inhabitants, or 2,638,585 people, comprising 85% of the estimated total population of the state, furnish an exceptional opportunity to study the prevalence of the prominent diseases from week to week and their fatality at different seasons and in various places.

One hundred cases of smallpox, 4,100 of scarlet fever, 6,772 of diphtheria and croup, 2,605 of typhoid fever and 12,511 of measles were reported during the year, under the law requiring notification of diseases dangerous to the public health each month, in order that suitable measures may be taken at once in case of undue prevalence of any one or them.

The examinations of sewer outlets during the year were directed chiefly to outlets into Boston harbor and to flats and tidal waters from which shellfish are taken as food. By request of the city of New Bedford, the Board investigated certain flats and tidal waters near that city and found sewage bacteria in quahaugs and shellfish near certain sewer outlets, with the result of such precautions being taken as to prevent the sale of such dangerous food.

Of 125 applications for advice upon matters relating to water supply, sewerage and sewage disposal, requiring the careful consideration of the Board, 75 related to water supply, 12 to sources of ice supply and 30 to sewerage, drainage and sewage disposal. More than one hundred pages of the report are devoted to the Board's advice in answer to these inquiries and, in connection with the same subject in previous reports, constitute an exhaustive consideration of the questions involved for reference and permanent use.

One hundred and seventy-two of the 353 cities and towns in the state, representing about 92% of the population, are now provided with public water supplies and show a correspondingly

diminished death-rate to less than 2 per 10,000 from typhoid fever as the most striking index of improved conditions of the public health.

For three cities and six towns, in furtherance of their custom, the Board established, during the year, rules and regulations for preventing the pollution and securing the sanitary protection of ponds and streams used as water supplies. The experiments with salts of copper to destroy disagreeable odors and taste of drinking water are not yet conclusive.

From an examination of a few selected industries, cutlery grinding, stone cutting and polishing, cigar making, boot and shoe making, rag sorting, the rubber industry and the lead industry, the Board recommends a codification of all laws relating to industrial pursuits and to sanitation of factories and workshops, the establishment of standards of ventilation, the enactment of some measure against spitting upon floors of workshops, factories and other confined spaces, and of more explicit phraseology than is now in existing laws.

The investigations with regard to the examination of public water supplies, water supply statistics and records of rainfall and flow of streams, purification of sewage and water and filtration of water comprise more than one-half of the bulk of the report, in continuation of similar inquiries which have been made for many years, and altogether place the Board as one of the foremost authorities in these vital measures of public health.

Under the food and drug inspection statute, 1,997 samples of milk, 2,799 of other food and 855 of drugs were examined during the year. Of the total, 8,651, those found adulterated or not up to the requirements of the law, were 26.6%. There were 62 prosecutions with 57 convictions.

Beginning with the year 1895, the Board has issued 241,562 bottles of diphtheria antitoxin with an enormous saving of life and with a reduction in the death-rate from that disease to 2.3 in the year 1904. From April 1 to Sept. 30, 1904, there were 494 specimens from 94 cities and towns examined for the bacilli of tuberculosis, of which 212 were found positive. 61 towns sent 204 samples of blood to be examined for typhoid fever, of which 158 were negative and 24 blood films showed the malaria parasite in 40 cases.

Under the familiar heading of Health of Towns one notices chiefly the enormously increased activity of local boards of health. Seventeen have laboratories for investigating sources and causes of disease.

Of Dr. Abbott, who died on Oct. 22, 1901, the Board well says that he was the able, devoted and untiring officer of a service to which he gave, with enthusiasm, the best years of his life. As a young man his strength was devoted to the perilous duties of the volunteer surgeon in both army and navy during our Civil War, and he spent his last twenty-two years in an equally determined struggle for the safety of the lives of his fellow-men, while secretary and executive officer of the Board.

As his successor, the Board has been fortunate in their appointment of Dr. Charles Harrington, an able and accomplished sanitarian of established reputation and character.

LOWELL INSTITUTE LECTURES ON CERTAIN PREVALENT NERVOUS DERANGEMENTS.

The first lectures of the last Lowell Institute course of this year were begun this week before a large audience by Dr. James J. Putnam, professor of neurology in the Harvard Medical School. As indicated in the synopsis of the course, Dr. Putnam will aim in these lectures to present in a semi-popular way certain of the modern ideas regarding prevalent nervous disorders and their significance, both to the individual and to the community at large. The topics of the various lectures are summarized as follows: The Nervous Health of the Community and the Influences Tending to Maintain and to Impair it; Influences Tending to Impair the Nervous Health of the Individual, especially Emotion and Fatigue; The Subconscious Life in its Medical Aspects; Correlations between the Mental and the Physical—Function and Structure, The Power of Adaptation Considered in its Medical Relations; Survey of our Means of Preserving Nervous Health—Mental Influences, Ideas and Habits.

Under these comprehensive headings, Dr. Putnam proposes to discuss matters which are evidently of most vital importance, and about which there is much superficial theorizing and speculation. Judging from the first lecture held Monday evening, and from Dr. Putnam's established reputation as a man of broad and general mind, it is not to be questioned that those who follow the lectures from beginning to end will take away with them a thoughtful interpretation of the best modern thought on many of the most complex questions of our time.

MEDICAL NOTES.

TROPICAL MEDICINE IN BERLIN. — A department of tropical diseases and hygiene, according to the *British Medical Journal*, has been established in connection with the Berlin Institute of Infectious Diseases. Dr. Claus Schilling has been appointed head of the new department. He took his doctor's degree at Munich, in 1895, and was afterwards assistant in the University Pathological Institute under Professor Bollinger. Later Dr. Schilling accepted a post in the Bacteriological Laboratory of the Imperial Health Bureau at Berlin. In 1900 he went out as Government Medical Officer to Togo. For a year past he has been working in the Berlin Institute of Infectious Diseases. Dr. Schilling is the author of many contributions to bacteriological and pathological literature.

ARROW POISONS. — Various forms of arrow poisons have been studied previously and now, according to the *Lancet*, Mr. Louis W. La Chard has been investigating certain very deadly poisons used by the native of Northern Nigeria. Two poisons were discovered, one vegetable and the other animal. He was able to isolate a variety of ingredients of the vegetable poison and found that it probably contained a highly toxic soluble alkaloid. Three specimens of the animal poisons were examined and shown to be made up of purulent and decaying matter, the effect of which is to produce ptomaine poisoning. The arrow heads are smeared with both poisons, but it is Mr. La Chard's opinion that either would cause death.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, March 14, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 43, scarlatina 39, typhoid fever 3, measles 205, tuberculosis 76, smallpox 0.

The death-rate of the reported deaths for the week ending March 14, 1906, was 21.73.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, March 10, 1906, was 250, against 214 the corresponding week of last year, showing an increase of 36 deaths and making the death-rate for the week 21.90. Of this number 124 were males and 126 were females; 242 were white and 8 colored; 167 were born in the United States, 80 in foreign countries and 3 unknown; 58 were of American parentage, 162 of foreign parentage and 30 unknown. The number of cases and deaths from infectious dis-

eases reported this week is as follows: Diphtheria, 53 cases and 6 deaths; scarlatina, 28 cases and 2 deaths; typhoid fever, 3 cases and 4 deaths; measles, 185 cases and 3 deaths; tuberculosis, 78 cases and 31 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 45, whooping cough 1, heart disease 30, bronchitis 7 and marasmus 3. There were 7 deaths from violent causes. The number of children who died under one year was 43; the number under five years, 74. The number of persons who died over sixty years of age was 63. The deaths in public institutions were 73.

There were 2 cases reported from cerebrospinal meningitis during the week.

HOUSE OFFICER ALUMNI ASSOCIATION, MASSACHUSETTS GENERAL HOSPITAL. — Arrangements are being made for the formation of an alumni association of the past house officers of the Massachusetts General Hospital. It is proposed to hold the first meeting at the Massachusetts General Hospital on the afternoon of March 24, when the newer parts of the hospital will be open for inspection and clinical demonstrations held for the benefit of the members. In the evening there will be a dinner at the Hotel Vendome.

A LOVING CUP TO DR. HENRY P. BOWDITCH. — At a meeting of the Bowditch Club, March 6, which followed a dinner for the members and certain invited guests, Dr. Henry P. Bowditch, for whom the club was named, was the recipient of a silver loving cup as a gift from the members, presented by the president, Dr. Allen Cleghorn. Dr. Bowditch responded in an appreciative speech. Later in the evening Dr. R. H. Fitz gave personal reminiscences of his and others' work in the development of our knowledge of appendicitis.

BOSTON LYING-IN HOSPITAL. — The work of the Boston Lying-in Hospital, which is recognized as one of the leading maternity hospitals in this country, shows that during the last year the number of patients treated in the hospital itself was 671, and that 669 children were born and cared for. The average length of stay in the hospital of the mothers was slightly over sixteen days, and there were but eleven deaths. The out-patient department treated 1,915 patients, with a total number of visits of 28,530. The valuable factor of the out-patient department work is that mothers are attended by trained nurses, graduates of the hospital training school. The report of the visiting physician makes the welcome statement that fewer patients were taken care of this year than last, due to the fact

that those in comfortable circumstances applying to the hospital were transferred to the care of the younger members of the staff who were willing to undertake their care for a moderate fee. It is hoped by this means to expose the hospital less to the reproach of pauperizing the community in the type of case received in its wards. The training school has been highly successful, and applications are numerous for entrance to the school. Sixty applicants were rejected during the year. The hospital needs improvements for the completest carrying out of its work and an appeal is made to the charitably disposed to meet these continual demands.

NEW YORK.

BEQUESTS.—Among the charitable bequests made in the will of the late Mrs. Frederica Talman are \$5,000 to the Faith Home for Incurables and \$1,000 to the Brooklyn Home for Consumptives.

GIFTS TO BROOKLYN CHARITIES.—Mr. Peter Wyckoff, who recently distributed \$50,000 among five charitable institutions in Brooklyn, has now made an additional gift of \$10,000 to the German Hospital in Williamsburgh.

DEDICATION OF ST. FRANCIS HOSPITAL.—Archbishop Farley dedicated the new St. Francis Hospital, in the Bronx, on March 1. This institution, which was organized in 1865, and was formerly located in East 5th Street, Manhattan, now occupies the entire block bounded by 142d and 143d streets and St. Ann's and Brook avenues, and has a capacity of four hundred beds.

A HOSPITAL AT MOUNT KISCO.—A meeting was held on March 5, under the auspices of the District Nursing Association, for the purpose of organizing a hospital to be located in the northern part of Westchester county, where the residents regard such an institution necessary. It is probable that the selection of Mount Kisco will be made for the new hospital, and a piece of property there, containing two small houses suitable for the work, has been offered the Association.

RESOLUTIONS AGAINST TRANSFER OF DYING PATIENTS.—Impressed with the need of action in consequence of a case recently reported to him in which a woman in moribund condition was hurried from the New York Hospital to Bellevue and died in the ambulance on the way, Coroner Harburger, chairman of the Board of Coroners, called a special meeting of the board for March 10. At this meeting vigorous resolutions protesting against the practice of transferring dying patients from one hospital to another were adopted. The

concluding resolution is to the effect that if the warning given is disregarded, the Board of Coroners will take stringent measures to bring the offenders to justice.

SUBWAY CONSUMPTION.—The day after Dr. Soper's report was made public, Dr. Philip O'Harlon, one of the coroner's physicians, announced the discovery of an affection which he designates "subway consumption," due to the inhalation of these steel particles. This was in consequence of the pulmonary conditions found at the autopsies of two subway track walkers who died recently, which were made by him in the presence of Dr. Soper and Dr. John H. Larkin, instructor in pathology in the medical department of Columbia University.

A SEASIDE HOSPITAL FOR TUBERCULOUS CHILDREN.—John D. Rockefeller has offered \$125,000 to the New York Association for Improving the Condition of the Poor for the erection of a permanent seaside hospital for children suffering from surgical tuberculosis, on condition, first, that the Association shall raise a like amount by June 30 next; and, second, that the maintenance of the hospital, by endowment or otherwise, shall be assured. Towards fulfilling the first condition nearly \$50,000 has already been subscribed, and it is believed that the balance will be secured without difficulty, as the success of the Association's temporary hospital for this class of patients at Sea Breeze, Coney Island, has demonstrated the need of a large permanent institution of the kind.

TOO MUCH DIPHTHERIA; TOO LITTLE ANTIDOTOXIN.—In view of the recent increase in diphtheria in the city, Health Commissioner Darlington has issued an appeal to the general public, as well as the medical profession, for the more prompt and general use of antitoxin. At present the average percentage of death in cases of this disease is 14, and he expresses his conviction that with a proper resort to the antitoxin this could be reduced to 2%. During the week ending March 3 the number of cases reported from it was 175, as against 374 in the preceding week, and the number of deaths from the disease was 61. This appears to be a "measles year." Ever since the beginning of 1906, more than 1,000 cases have been reported each week, and during the week ending March 3 the number amounted to 1,003. It is gratifying to note, however, that notwithstanding the increased number of cases, the mortality from measles was less in this week than in that ending Feb. 3.

STATE COMMISSION IN LUNACY. — It is announced that Dr. M. V. Mabon, president of the State Commission in Lunacy, has tendered his resignation of that position, and is to be appointed superintendent of the Manhattan State Hospital for the Insane on Ward's Island, New York, in the place of the late Dr. Emmet C. Dent.

ANNUAL REPORT, COMMISSION IN LUNACY. — The seventieth annual report of the State Commission in Lunacy has just been made public. While, as previously announced, the number of new cases of insanity developing was smaller during last year than in the year preceding, and but slightly in excess of that in 1903, the number of insane in the various institutions of the state was 27,300 on the first day of June, 1905, a ratio of one person to 299 of the general population, as against 17,275 in 1902, a ratio of 1 to 377 of the general population.

MONTHLY MORTALITY, NEW YORK. — The weekly reports of the Health Department show that during the month of February the mortality in the city represented an annual death-rate of 18.81, as against 18.72 in January and 19.77 in February, 1905. The corrected death-rate, excluding non-residents and infants under one week old, was 17.76. Among the diseases in which there was an augmented mortality were the following: The weekly average of deaths from measles increased from 20.5 in January to 45.75 in February; the weekly average from pulmonary tuberculosis, from 164.75 to 171.75; from influenza, from 8.75 to 9.75, and from epidemic cerebrospinal meningitis, from 17 to 18.25. Among the diseases in which there was a decline in fatality were the following: The weekly average of deaths from acute bronchitis decreased from 50 to 39.25; from pneumonia, from 175.5 to 163.75; from bronchopneumonia, from 121.75 to 120; from cancer, from 56.5 to 55.25; from organic heart diseases, from 114.75 to 112, and from Bright's disease and nephritis, from 125.5 to 108. The mortality from cerebrospinal meningitis was 50% smaller than at the same period of 1905, and it is stated that the general death-rate for the week ending Feb. 3, namely, 18.01, is lower than that of the corresponding week in any year of which the Department has record.

AN ATHLETIC FIELD FOR COLUMBIA. — Plans have been reported for the construction of an athletic field for Columbia University, which is to cost \$1,000,000, and will be one of the largest and finest in the world. The ground on which it is purposed to build it is to be reclaimed from

the Hudson River, and it will extend four blocks, from 116th Street to 120th Street, and from the present shore line out to the limit which the United States government permits for piers in the river. On the filled-in inclosure there will be constructed three separate fields, one for the use of the University, and two on either side of this, north and south, for the Public Schools Athletic League and for a public playground. On the roof of the stands to surround the university stadium, which will have seats for 35,000 spectators, there will be located recreation grounds for the public, similar to the city's recreation piers now in use. While the consent of the municipal authorities to the project has not as yet been obtained, it is believed that, in view of the great public benefit to be derived, without any expenditure on the part of the city, there will be no difficulty in securing this. It is also stated that there is every prospect of readily raising among the friends of Columbia the large amount required for carrying out the undertaking.

A FIELD HOSPITAL FOR THE NATIONAL GUARD. — The New York National Guard is to have a field hospital, which is to be attached to headquarters and will be used in caring for the sick and wounded when the guard is in camp or when performing riot duty or engaged in other active service. The new hospital will not in any way interfere with the present regimental hospital corps. It is proposed, when the troops are in the field, that all sick and wounded men in the care of the regimental hospital who have not recovered in twenty-four hours shall be turned over to the field hospital, as is done in the regular army. The latter will be equipped with a portable laboratory, with a view to the prevention of disease by the examination of water, food, etc. The hospital staff will consist, in time of peace, of four officers and forty-six enlisted men. Dr. William S. Terriberry of the Twelfth Regiment, who served as a medical officer in the Spanish-American war, is to be in command of this new field hospital, and he will be assisted by Dr. William E. Butler of the Twenty-third Regiment, and Dr. Thomas A. Neal, late of the Seventh Regiment, who is pathologist to the New York Infant Asylum. The fourth officer, it is stated, has not yet been selected.

SANITARY CONDITIONS OF THE SUBWAY. — Dr. George A. Soper, the consulting sanitary engineer, has made an elaborate report to the Rapid Transit Commission, in which, in substance, he

shows the sanitary conditions of the subway to be on the whole good, in spite of the fact that its sanitary administration is bad. After critical and severe criticism in various particulars, he states that there were, on an average, more than twice as many bacteria found in the air of the streets as in the air of the subway, excepting after rains, when fewer were found outside than inside. The average number of bacteria which settled from the air in fifteen minutes and were developed upon the plates was: In the subway, 500; outside, 1,157; difference, 657. The average number of bacteria found in filtered air was 3,200 per cubic meter of air in the subway, and 6,500 per cubic meter of air in the streets; difference, 3,300. The number of bacteria in the air of the subway varied with the amount of travel, being most numerous when the number of trains and passengers was largest. The pneumococcus was found capable of retaining its virulence for twenty-three days in the subway, while according to Dr. Wood, who made studies of the resistance of this organism for the Commission for the Investigation of Acute Respiratory Diseases of the New York City Department of Health, the pneumococcus is killed in four hours in sunlight. In samples of subway dust examined a large percentage of minute steel particles, the result of friction, was found.

Obituary.

CHARLES A. LINDSLEY, M.D.

Is the death of Dr. Charles A. Landis, of New Haven, which has occurred within the week, the state of Connecticut loses a valuable public servant and the medical profession a man of distinction. Since 1884 Dr. Landis has been in the position of secretary of the Connecticut State Board of Health and for many years, previous to this appointment he had been a professor of the Yale Medical School. At that school he had successively occupied the positions of professor of materia medica, of therapeutics, and of professor of the principles of therapeutics, and on sanitary system. He had a special collection of resources of the materia medica, and a historical library. His other work was connected in connection with the Board of Health, and he did all the necessary work connected with the interests of public hygiene. He was a distinguished biologist and a very competent physician, the surgeon general of the state, and the author of a valuable work on the diseases of the oyster-belt of the Connecticut coast.

Miscellany.

HUMAN BLOOD PRESSURE AND PULSE AS
AFFECTED BY ALTITUDE

CHARLES FOX GILBERT, M. D., HON. W. H. HENRIKSEN, and others, have described the results of a study of the effect of a large number of blood pressure measurements at Colorado Springs and at Pike's Peak, the latter having an altitude of 6,900 feet, the former that of 14,000 feet. It was ascertained that the average blood pressure of residents of Colorado Springs who had been there for over a year or more was slightly lower than that of dwellers at the sea level, while the Colorado natives showed the increase in altitude, said to be present in plateau dwellers. Tests of twenty-two healthy residents taken from Colorado Springs to the top of Pike's Peak, in a railway car without any muscular effort, showed that at the end of three and one-half hours the blood pressure had fallen from 126 mm. to 118 mm., and the pulse rate had gone from 80 to 90 per minute. The authors found a rough ratio between pulse rate and blood pressure; the more rapid the pulse, the lower the blood pressure. It was also noted that when a pulse rate was but little affected by an altitude of 14,000 feet, the blood pressure was also more constant, that cases of mountain sickness were accompanied by a fall in blood pressure and a rapid pulse rate. The conclusion is that cases of high tension are likely to be benefited by being sent to high altitudes, while the change would probably be an undesirable one for patients in whom the blood pressure is abnormally low at sea level. *Medical Record*, March 10.

THE NEW HAVEN MEDICAL ASSOCIATION.
RESOLUTIONS OF THE COMMITTEE ON PATIENT
MEDICINES.

3. *Resolved*: That the Secretary of the New Haven Medical Association be requested to write the following firms, Kinnow Tabbet Company, Fraser Tabbet Company, George C. Fris, Horbaker's Food Company, Johnson & Johnson, Keck & Matteson, Mellin's Food Company, Schuchman & Co., Seabury & Johnson, Adair's Meat Food Company, Wm. Lee & Co., for information, and to inform them that the Association is officially, when they are so notified, members of the Protestant Association of America.

2. *Relevance*—Despite the reason that the *Journal* is devoted to the New Historic Movement, it is not devoted to all aspects of the movement. The *Journal* is devoted to the contributions of the movement to the study of the American continent and the Caribbean.

$\mathcal{R} = R_1 \oplus \cdots \oplus R_n$ is a \mathbb{Z} -module, then \mathcal{R} is a \mathbb{Z} -module.

CHANGES IN THE MEDICAL CORPS U. S. NAVY
FOR THE WEEK ENDING MARCH 10, 1906.

R. W. PLUMMER, passed assistant surgeon. Detached from the naval recruiting station, Kansas City, Mo., and ordered to the naval recruiting sub-station, St. Joseph's, Mo.

W. N. McDONELL, assistant surgeon. Ordered to the "Yankee."

L. H. SCHWEIN, acting assistant surgeon. Ordered to the "Celtic."

J. B. DENNIS, surgeon. Detached from the Naval Hospital, Pensacola, Fla., and ordered to the Naval Proving Grounds, Indian Head, Md.

F. L. BENTON, surgeon. Detached from the Naval Hospital, Brooklyn, N. Y., and ordered to the Naval Hospital, Pensacola, Fla.

SOCIETY NOTICES.

AMERICAN MEDICAL ASSOCIATION CHORUS.—I have been asked to augment to thirty voices a chorus of physicians (who have sung together for some years past at the annual dinner of the Massachusetts Medical Society) in order that we may furnish some music at the President's Reception during the coming meeting of the American Medical Association in June, 5-8. We have now forty-five names on our chorus list. We must have five or six reinforcements before next June. Any one knowing of any good singers in the profession (graduates or undergraduates) will please suggest names (their own or others) to

RICHARD C. CABOT, M.D.,
190 Marlboro St., Boston

NEW YORK SKIN AND CANCER HOSPITAL.—The Governors of the New York Skin and Cancer Hospital, Second Ave., cor. 10th St., announce that Dr. L. Duncan Bulkley will give four special lectures on "The Principles and Application of Local Treatment of Diseases of the Skin," on Wednesday afternoons, March 21 and 28, and April 4 and 11, and that Dr. William Seaman Bainbridge will give a clinical lecture on "Malignant and Non-Malignant Growths," on Wednesday, April 18, in the Out-Patient Hall of the hospital, at 4.15 o'clock. The lectures will be free to the medical profession.

WILLIAM C. WHITE,
Chairman of Executive Committee.

NEW ENGLAND OTOLOGICAL AND LARYNGOLOGICAL SOCIETY.—The regular meeting of this society will be held in the Out-Patient Department of the Massachusetts General Hospital, Friday evening, March 16, at 8 o'clock. Papers: Dr.

H. A. Barnes, "Should Cultures be taken before operating on the nose and throat?" Dr. H. P. Mosher, "Fatal Meningitis after removal of the Middle Turbinate." Dr. G. L. Tobey, Jr., "Fatal Meningitis after operation on the Ethmoid Labrynth." Dr. F. C. Cobb, "The connection between certain ocular and nasal conditions." Dr. G. H. Powers, Jr., "Submucous resection of the septum." Dr. G. L. Tobey, Jr., "Submucous resection of the septum." Dr. A. Coolidge, Jr., "One cause of chronic hoarseness in children."

PHILIP HAMMOND, M.D., Secretary.

APPOINTMENTS.

CARNEY HOSPITAL.

The following appointments have been made at the Carney Hospital: Dr. W. T. Counihan, pathologist, Dr. P. S. Smyth, assistant ophthalmic surgeon, and E. A. Austin, chemist.

RECENT DEATHS.

DR. ROBERT C. HUTCHINSON, surgeon of the American Liner "St. Louis," and one of the best known medical officers in the transatlantic steamship service, died suddenly of pneumonia on board the "St. Louis" on Feb. 27, when the vessel, westward bound, was in mid-ocean. During his brief illness he was attended by Dr. Reynier Van Nessel, the medical faculty of the University of Pennsylvania, a passenger on the steamer, who when summoned to Dr. Hutchinson's bedside recognized in him a classmate at the University Medical School and a fellow-interne at one of the Philadelphia hospitals.

DR. FRANK J. FREEL of Brooklyn, N. Y., died of pneumonia on March 9, at his summer home, Stony Brook, Conn. He was a graduate of the Long Island College Hospital, and forty-eight years of age.

DR. SANFORD W. ADAMS, police surgeon of Mt. Vernon, Westchester County, N. Y., died at his home in that city on March 7, at the age of twenty-nine years.

DR. GROVES BEARDSLEY of Syracuse, N. Y., a retired surgeon of the United States Navy, died on March 7, at Atlantic City, N. J.

[illegible]

tance into the left ureter showed a transparent, non-albuminous urine without sediment, but a specimen from the right ureter contained albumin in very slight amount and granular cells and leucocytes such as were found in the bladder urine; the catheter passed to the right kidney pelvis showed a slight amount of aseptic renal retention. Filling the right kidney pelvis with sterile borie solution by means of the ureter catheter exaggerated the pain she complained of in her right loin. A second examination after the patient had been in bed instead of on her feet showed no retention in the kidney pelvis.

The epithelium coming wholly from one kidney, the aseptic renal retention when the patient had been on her feet and its absence when she had been in bed, as well as the pain on distending the renal pelvis, all seemed to point pretty definitely to the movable kidney as the cause of her right lumbar pain. The right kidney was cut down upon and fixed in place. The patient was seen a month later, at which time there had been no return of her pain, but too short a time had elapsed to tell whether or not this relief would be permanent.

Beside the pain in this prolapsed kidney, which was undoubtedly due to dragging on the pedicle, it is interesting to note that we had an aseptic renal retention that had begun to cause changes in the renal pelvis. These changes were apparently a maceration and desquamation of the pelvic epithelium, — changes that would probably have made the organ particularly susceptible to infection. This aseptic renal retention does not exist in all prolapsed kidneys, but when it is present it should be considered as an extra-indication for fixing the kidney in a position that will facilitate its drainage.

CASE IV. A man, forty-three, with a septic retention of his left kidney pelvis. This man came to the Boston Dispensary in the fall of 1905 in the service of Dr. C. M. Whitney, through whose courtesy I saw him. Though he denied venereal infection, it seems possible that he may have been mistaken as to this. His trouble began eleven years ago with a slight urethral discharge, which was followed by a subacute epididymitis, according to his story. Shortly after this time he began to have backache, suprapubic pain and pain in his groins. Since about 1900 he had had a turbid urine with nocturnal frequency (four or five times). He had little pain on micturition. For two years he had had bladder irrigations without effect. When he first appeared at the clinic he showed a chronic prostatitis and vesiculitis. His urine, which was very turbid, did not, however, clear with the treatment of his prostate. Neither kidney was tender nor palpable. Cystoscopic examination showed a tolerant bladder with a slight cystitis of the base. There was a curious hood-like puckering high up on the posterior wall which may have been congenital in origin or due to some former ulceration. The right ureter was on a considerable papilla; it was normal in appearance and emitted unusually strong and frequent spurts of clear urine. The left ureter was also on a papilla; it was "slipper shaped" and a bit of muco-pus could be seen protruding from the ureteric orifice. Pushing against the posterior bladder wall with the beak of the cystoscope made the ureter gape open and assume the appearance of the "golf hole" ureter of Fenwick. A catheter passed into the left ureter very easily and, left in place for twenty minutes, gave but a few drops of turbid fluid; when passed to the kidney pelvis, the

catheter excavated 2 oz. of turbid fluid in a short time. This fluid contained a trace of albumin, .50% of urea, a little blood, some epithelium, a large amount of pus and a great number of bacteria. No tubercle bacilli could be found in cover slip preparations. A catheter specimen from the right ureter showed a transparent urine of normal color containing a slight trace of albumin, urea 2.27%. The sediment, which was very slight, showed a single cast, a little normal blood and a few epithelial cells, the blood and epithelial cells probably due to a slight injury of the ureteral membrane by the catheter. The ureteric jets on the right were at times as frequent as every five seconds and occasionally there would be twenty to thirty drops in a jet, showing a very actively secreting organ.

This man was under observation for a considerable time and repeated examinations gave practically the same results. Washing out his left kidney pelvis made his urine considerably clearer temporarily and lessened his nocturnal frequency. He should submit to kidney drainage or nephrectomy, which was advised him.

This patient, who had been supposed to be suffering from a cystitis for which he had received bladder irrigations for two years, illustrates in a striking way the extent to which a renal suppuration may occasionally go without giving symptoms that call particular attention to the kidney; also the fallacy of expecting to find a palpable or tender kidney in all renal suppurations. At no time was I able to detect any mass or tenderness in his left loin.

CASE V. A woman of thirty-nine, referred for examination in December, 1905, by Dr. H. Lincoln Chase. She had been delivered of her eighth child seven weeks before. Immediately after delivery Dr. Chase had noticed a considerable mass in her right lumbar region, which was elastic and the shape of an enlarged kidney. It was movable and could be separated from the liver above. This mass gave considerable pain for the first three weeks following labor; since then it had been painless, though it had gradually increased in size. A week before she was seen she suddenly became blind in her left eye, due, it is said, to a retinal hemorrhage. The blindness persisted at the time of examination, though it was clearing up some when this woman was last seen.

Her urine, which was very slightly turbid, contained leucocytes in small numbers and epithelial cells. Tubercle bacilli were found in it. The patient occupied the same room with her husband, who had advanced phthisis, and the presumption was that she had a tuberculosis of her right kidney. The bladder, which was perfectly tolerant, showed a little redness about the left ureter. The right ureteric orifice was small and normal looking. A No. 6 catheter could be introduced into the right ureter about one and one half inches, but could not be made to go any further. No urine could be gotten. A catheter passed into the left ureter perfectly easily, and a half ounce of urine, of about the same turbidity as the bladder specimen, was obtained, in a short time. In this urine tubercle bacilli were found. At a subsequent examination, three weeks after the first, the findings were the same.

The knowledge gained in this case was of considerable importance and raised several interesting points. On the one hand we found that the supposedly well kidney was not an entirely sound one, and while it was at that time perfectly competent it could not be depended upon

to continue so for any length of time. On the other hand the finding of tubercle bacilli in the left kidney, together with the obstruction low down in the right ureter, raised the hope that the condition in the right kidney might be purely an hydronephrosis due to an impacted calculus, and that if relieved before too long a time elapsed, the kidney might be rapable of a certain amount of work and of helping out to some extent the kidney known to be tuberculous. The patient has not as yet been willing to submit to operation.

CASE VI. An Italian woman of about thirty, who entered St. Elizabeth's Hospital in November, 1905, in the service of Dr. Kingman, to whom I am indebted for the privilege of reporting the case. She spoke but little English, and her complaint, so far as could be learned, was of backache and dysuria. She had a heavy uterus in the third degree of retroversion, with nothing else that could be made out on pelvic examination. Her urine showed the characteristics of a chronic cystitis. It was supposed that her pain and cystitis both depended on the abnormal position of her uterus, so a ventral suspension was done. Immediately after the operation the patient had a rather profuse haematuria lasting some days. This gradually cleared up, but her pain and frequency remained and her urine continued to show microscopic blood. The bladder, on examination, was found difficult to cleanse, and very intolerant to distention; it would hold no more than 3 oz. without giving great pain. The cystoscope showed that the trigone and lateral walls of the bladder were inflamed, thickened and covered with great flakes of mucus-pus. With the prism turned upward, a moderate sized stone could be plainly seen. The curious position of the stone was accounted for by the fact that the ventral suspension had pulled up the bladder in such a way as to make it an inverted cone, and that when I had introduced the cystoscope it had slid between the bladder base and the stone, raising the stone from the floor. Litholapaxy was performed by Dr. Kingman the next day. The stone was very soft and had as a nucleus what seemed to be a bit of mucous membrane. The patient went home in a few days entirely relieved of her pain and frequency and with a urine that was clearing up rapidly. Even after this calculus had been seen with the cystoscope, bi-manual examination failed to detect its presence.

CASE VII is one of cancer of the left kidney. The patient was a married woman, fifty-seven years old, seen with Dr. W. A. Brooks, through whose courtesy I report the case.

When the patient was seen in January, 1906, she had a painless haematuria that had persisted for two weeks. Four weeks before she had passed bloody urine at one micturition. There was a vague history of a little pain and of a tender spot in the left loin during the summer of 1905. The left kidney was not tender and was not definitely enlarged. There were no other localizing symptoms. The urine was so bloody that it was almost impossible to distinguish any formed elements other than blood globules. The bladder was very tolerant and easily washed clean.

Cystoscopic examination showed an extremely pale but otherwise normal bladder, with rather infrequent jets of what appeared to be pure blood coming from the left ureter. The first time she was examined, the bladder medium could not be kept clear a sufficient time to catheterize the right ureter. The urine from it, however, appeared to be clear. Five days later, the bleeding being a little less, by the use of greater distention I was able to keep the medium clear a suffi-

cient length of time to catheterize the right ureter. The right urine had a slight trace of albumin, 1.39% of urea, a few blood globules (accidental, due to trauma of the catheter), a few leucocytes, a few round, spindle and oblong cells; no casts; in other words, the urine showed a kidney of fair capacity.

The absence of any considerable pain, together with the absence of casts or of any evidence of suppuration, led me to the probable diagnosis of malignant disease, which was heightened by the negative findings of radiography. Somewhat later the bleeding increased and the patient began to have occasional attacks of colic, due to the expulsion of clots.

Owing to Dr. Brooks' departure for Europe, the patient was operated upon by Dr. Mixer Feb. 2. The left kidney, which was removed, showed on its anterior surface near the lower pole, a malignant mass as big as a plum, extending from the cortex to the pelvis. It had apparently not burst through the capsule. The right kidney has shown itself to be perfectly competent and the patient is making a good recovery.

CASE VIII shows another instance of painless haematuria due, however, to a different cause. The patient was a Chinese merchant, aged forty-three, referred to me by Dr. E. M. Greene.

His previous history was unimportant. For three months he had been passing bloody urine, the greater part of the time without pain. For a little while he had had some frequency of micturition. He had noted that there was often no bleeding at night. There was no symptom that gave any hint as to the source of this man's bleeding. Palpation was negative. His urine, which was bright red, contained a considerable number of clots, and no formed element other than normal blood cells were found. He had a moderately tolerant bladder, but the bleeding made it difficult to wash it clean.

Cystoscopic examination, made through a slightly bloody medium, showed a wavy mass with hemorrhagic patches on the right side of the bladder near the right uterine orifice. This mass was undoubtedly a papillomatous growth of some type for which operation has been advised, but not yet carried out.

In all of the above cases the cystoscopic examination added very definitely to the knowledge that had been obtained by the other methods of study. In Case III this knowledge simply corroborated and added some interesting, but perhaps unimportant, data to what was already known. In the other cases, with the exception of Case VI, in which sounding or digital examination of the bladder would doubtless have given the same result, cystoscopy gave valuable knowledge that could have been acquired in no other way with so little danger or discomfort to the patient.

In the cases of painless haematuria of renal origin, cystoscopy is of particular value, allowing one to tell definitely which kidney the bleeding is from before the other localizing symptoms—pain, tenderness and increased size, have appeared. The great value of this early localization in cases of malignant disease is self evident.

TYPHUS FEVER IN MEXICO. Dr. Bernardo Jacoby, of New Orleans, has reached Mexico City to make a study of typhus fever. There have been 130 new cases since March 1, with 42 deaths. The sanitary campaign in the poorer quarters of the city is vigorously prosecuted. *American Medicine*

CEREBRAL SEIZURES WITH SUBOCCIPITAL PAIN: MILIARY CEREBRAL AND GROSS VERTEBRAL ANEURYSMS.*

BY W. D. RUSTON, M.D., AND E. E. SOUTHARD, M.D., BOSTON.
From the Pathological Laboratory of the Boston City Hospital.

THE following case suggests the difficulty of diagnosis in cranial conditions anatomically simple. A woman of sixty-nine years presented a series of cerebral seizures without focal signs, leading to fatal issue in nineteen days. The seizures were ushered in by boring suboccipital pain. The autopsy revealed several successive voluminous hemorrhages so situated in various parts of the cerebrum that the fibres of the projection system were largely spared. The small cerebral arteries, both of the cortical and the ganglionic systems, were beset with miliary aneurysms. Both vertebral arteries opposite the junction of bulb and cord, showed gross aneurysmal dilatation.

I. Clinical History.—Widow of sixty-nine years. For a year before her last illness she showed a tendency to drowsiness in the daytime and would even fall asleep in company.

She was taken one evening, nineteen days before her death, with sudden, severe, suboccipital pain, described as boring and confined to a spot the size of a fifty-cent piece. The pain was at first attributed to neck strain, produced by gazing up at mural paintings the afternoon of the attack. The pain was followed shortly by projectile vomiting with retching. These symptoms persisted for two days. The day after the attack the pain became less severe and changed to a dull ache, constant in the original situation and varying in intensity, without, however, relation to movement or position of the head and neck. On the fourth and fifth days of the illness there were slight chills with sweating. Evening rise of temperature from 1° to 3° F.

Examined Nov. 1, 1905 (W. D. R.). Development good. Considerable adipose tissue. Mind clear. Attitude cheerful. Eyes: Movements normal; pupils react readily to light and distance. Head: No tender spots; no bruit heard; no rigidity or retraction of neck; no inequality in sides of face; no paralysis of facial muscles. Tongue: Protruded straight, dry, coated, cleaning in center. Breath foul. Throat: Negative. Pulses: Regular, 68, of good volume with increased tension. Moderate degree of radial and brachial arteriosclerosis. Heart: Right border two finger breadths to right of right edge of sternum; upper border at third rib; left border in nipple line; apex in fifth space in nipple line; action regular; sounds of good intensity; systolic blowing murmur over aortic orifice; aortic second sound accentuated. Lungs: Negative, except for a few moist râles in both bases behind. Abdomen: Negative. Spleen: Not felt. Extremities: Normal. Reflexes: Superficial reflexes slow; knee jerks slow and equal; Kernig's sign absent; Babinski's sign absent. Leucocytes, 17,000.

The evening of Nov. 2 (eighth day of illness) came another attack of boring pain, localized as before, lasting eight or ten minutes. The mind wandered during the attack. There was steady improvement. The temperature remained slightly elevated. The pulse ranged from 60 to 68. The mind was clear. The attitude cheerful. The dull aching pain continued in the back of the head.

The morning of Nov. 13, after passing a comfort-

able night, the patient complained of a sudden cold feeling in the forehead. Consciousness became clouded. Coma and Cheyne-Stokes breathing set in with death in about two hours.

Clinical Summary.—Woman of sixty-nine, with moderate arteriosclerosis and an enlarged heart. Attacks of severe, boring pain, localized in an area the size of a fifty-cent piece, in the suboccipital region (first and eighth days). Slight chills (fourth and fifth days). Temperature slightly elevated with morning remissions. Leucocytes, 17,000. Death in coma two hours after a sudden cold feeling in the forehead (nineteenth day).

II. Autopsy Findings (E. E. S.)—Well developed woman of middle height. Nutrition good. No edema. Pupils equal, not dilated.

Trunk: Subcutaneous fat of abdomen 5 cm. deep; cavities normal; mesentery very fatty; mesenteric lymph nodes not palpable.

Heart: Considerable epicardial fat; heart much enlarged; valves normal, except for raised yellow areas of sclerosis in mitral leaflet; muscle of both ventricles unusually firm and without opacities; right ventricle 1 cm., left ventricle, 2.5 cm. thick; chambers contain freshly clotted and liquid blood; coronary arteries show nodular sclerosis. Lungs: Normal; post-mortem congestion of bases beginning; slight superficial fibrous thickenings at each apex; bronchial lymph nodes not remarkable. Spleen: 18 cm. long; capsule smooth and slightly thicker than usual; substance firm, not pulpy; Malpighian bodies made out; trabeculae slightly increased; splenic artery shows marked stiffening. Liver: Chestnut brown, firm; lobulation made out with difficulty. Gall bladder: Small, buried in smooth old adhesions; contains no stones. Pancreas: Normal. Gastro-intestinal tract: Normal on inspection and palpation. Kidneys: Strip readily, leaving a roughened surface; numerous small cysts over anterior surfaces of both kidneys; pea-sized aberrant adrenal, 2 cm. from hilum, midway between poles imbedded in anterior surface of right kidney; substance shows opacities suggesting fat. Pelves normal. Adrenals normal. Genitalia: Atrophic.

Head: Hair fairly thick and streaked with gray. Scalp: Strips readily. Calvarium: Thick (in places 1 cm.) and dense. Dura: Tightly adherent to calvarium over all, but inseparably adherent to occipital bone. Sinuses: Normal. Arachnoid villi: Slightly developed. Pia mater: Everywhere reddened by hemorrhage or dissolved blood pigment. The frank areas of hemorrhage involve the sulci of the anterior and mesial surfaces of the cortex cerebri in the area of distribution of the anterior cerebral arteries. The flanks and posterior pole of the brain show reddening, and congestion of superficial sulcal veins, but no fine injection. Over the sulcal veins of the vertex are slender streaks of fibrous thickening. Vessels: At base show diffuse and nodular sclerosis. Both vertebral arteries show fusiform aneurysmal dilatations, 0.75 cm. in diameter. The circle of Willis is apparently pervious. The primary branches of the middle cerebral arteries show nodular sclerosis in patches 0.5 to 1 cm. long.

Substance.—Convulsions flattened. Anterior pole of left hemisphere contains a core of clotted blood and tissue detritus occupying the centrum semiovale under the first and second frontal gyri. The clot is fresh and can be readily turned out from its bed above the forceps minor. The upper fibers of the forceps minor and anterior quarter of the tapetum have been de-

* Read Feb. 15, 1905, at a meeting of the Boston Society of Psychiatry and Neurology.

stroyed by the hemorrhage and show a moist, ragged, grayish surface. The hemorrhage approaches the surface in the gyrus rectus and about the olfactory lobes; thence the blood has oozed into the orbital and polar sulci.

A similar hemorrhage fills the white matter of the right anterior pole above the forceps minor, but has broken down the gray matter at the pole. The clots on the right side cannot be turned out so readily as those on the left. Small vessels with tightly adherent small masses of mixed gray and red clot are demonstrable in the bed of the hemorrhagic area. Fresh oozing into the cortical sulci has occurred on the right side as on the left. The ventricles contain no blood and no increase of fluid. Ependyma normal. Posterior parts of lateral choroid plexuses cystic. Basal ganglia, inter-brain, isthmus, cerebellum normal.

Miliary surrounded by effused blood.

Blood serum cultures from hemorrhage into right frontal lobe and from right basal ganglion remained sterile.

The pia mater and vessels were macerated out in running water by Mr. J. B. Ayer, and both the cortical and the ganglionic systems of arteries proved to show in their smaller branches numerous miliary aneurysms. These were sometimes saccular, sometimes fusiform in shape.

Anatomical Summary. General arteriosclerosis (aortic, coronary, cerebral, splenic, renal). Fusiform aneurysms of both vertebral arteries. Miliary aneurysms of cortical and ganglionic arterial systems.

Extensive multiple cerebral hemorrhages (of varying age) in substance of anterior poles of brain and elsewhere, with oozing into superficial pia mater.

Hypertrophy of heart, endocardial sclerosis, arteriosclerotic nephritis, apical scars of lungs, chronic pericholecystitis, chronic adhesive external pachymeningitis, chronic fibrous leptomenigitis, aberrant adrenal in right kidney.

III. Macroscopic Findings.—The microscopic examination was chiefly confirmatory of the gross findings. The organs of the trunk showed relatively more arteriosclerosis than the intracranial tissues. The kidney showed numerous advanced chronic changes with extensive arteriosclerosis, numerous atrophied glomeruli and tubercles. The lungs showed no signs of acute inflammation. The spleen showed numerous hemorrhages into the pulp and a heavier framework than usual, but failed to show acute alterations.

Numerous sections were made from the cerebrum, medulla and cord. The cerebral hemorrhages proved to be distinguishable into fresh hemorrhages, hemorrhages with numerous phagocytes containing undecomposed blood globules, and hemorrhages containing pigment phagocytes. Of the fresh hemorrhages, many were small dissecting hemorrhages about the smallest vessels; but very few of these vessels showed demonstrable ectasia or alteration in the elastica. The older areas exhibited numerous phagocytic cells ingesting blood globules, sometimes in scores. The most numerous phagocytes occur in the sulci in the neighborhood of the larger vessels. The pigment-phagocytes are generally distributed and have often lost their spherical shape. There are strikingly few signs of cellular exudation anywhere in the meninges, although an occasional large subdural vein will show a minute collection of cells of the lymphocyte series at a single focus in the adventitia. Signs of reaction on the part of the

nerve tissue are few. There is an occasional strip of the outer cortical layer, which shows a number of swollen neuroglia cells; but these are enmeshed among rather dense fibrils, and there is evidence of a general but focally varying superficial fibrillar gliosis, probably long antedating the hemorrhages and still condensing. The pyramidal nerve cells show considerable over-pigmentation.

Similarly in the region of the vertebral aneurysms the diffuse gliotic alteration of the superficial zone and in the neighborhood of the posterior roots is part and parcel of a more general process, exhibited equally in the medulla beyond the zone of immediate aneurysmal pressure. Nevertheless, we cannot exclude this gliosis from influencing in some degree the regionary pain. The vessels of the cord and medulla themselves show little alteration. There was no convincing evidence of alteration in the nerve bundles in the walls of the vertebral aneurysms. Slender collections of cells of the lymphocyte series lie in the connective tissues opposite the middle of the walls of the aneurysms, where breaks in the elastica and thinning out with occasional fenestration of the muscular layer occur.

IV. Remarks.—Aneurysms of the vertebral arteries, like those of the other cerebral arteries, are rarely made out in life and are usually discovered by medical examiners in cases of sudden death. v. Hofmann, 1894, mentions ten cases of aneurysm of vertebral artery with fatal rupture, over against twenty cases of Sylvian, thirteen cases of carotid, and ten cases of basilar aneurysm in the same series.¹ Curiously enough, the youngest victims of basilar aneurysm in v. Hofmann's series showed left vertebral aneurysm (a girl of ten dying suddenly in convulsions, and a boy of fourteen dying suddenly). From time to time, however, cases of vertebral aneurysm without rupture and with definite symptoms have been reported. As examples of these and for comparison with our own case, we have abstracted in particular the irritative case of F. Schultze, 1875, the slowly destructive case of Ladame and Monakow, 1900, and the case with fatal rupture of Rindfleisch, 1905.

F. Schultze, 1875, reported a case of aneurysm the size of a cherry in the left vertebral artery about one-half inch from the junction with the basilar artery, so placed as to compress the left seventh and eighth nerve roots.² The subject was fifty-six years old and labored of phthisis, showing no effects of the aneurysm save a pronounced *trismus*. The tie had lasted about a year, and consisted in brief rapidly recurring clonic contractions of the left side of the face, starting up or augmenting with speech or mastication. The intervals without it varied. The frontalis, ear muscles and palate were not involved. Pain was absent. There were no points of pressure or which to evoke the contractions.

Ladame and Monakow, 1900, reported a case of aneurysm of the left vertebral artery in a man of sixty-eight with a history of syphilis, who

tion at thirty.³ The symptoms began about two years before death with vertigo and attacks of angina pectoris. After a particularly violent apoplectiform attack, a cerebellar gait developed, with dysarthria, some dyspnea, cerebellar ataxia, and occasional pains in the left arm. After six months of such symptoms, the patient had a violent seizure with vertigo and vomiting, but without loss of consciousness. Thenceforward the patient always fell to the left, would no longer walk, stand or sit up, and showed loss of pain and temperature sense on the right side of the body, left abducens palsy, slight left ptosis, and narrowed left pupil. Swallowing became difficult, stupor and coma followed, with death two years after onset of earliest symptoms, forty days after the last seizure. The autopsy showed an aneurysm the size of a pigeon's egg of the left vertebral artery near its junction with the basilar artery. There was corresponding atrophy of the pons, cerebellum, olive, pyramid, and left acoustic nerve, with slight atrophy of the left fifth, sixth, ninth and tenth nerves.

Rindfleisch, 1905, reports a case of aneurysm of the right vertebral artery, with fatal rupture, in a woman of fifty-one.⁴ For ten years she had had attacks of asthma and edema of the legs. For three years she had had eructations and headaches. Three days before entrance to the hospital she had been taken with sudden eructations and pains in the back of the head. On the day of admission she had two attacks of stupor with facial cyanosis, transient Cheyne-Stokes breathing, and râles in the lungs. The first attack began with a feeling of terror and screams. In both attacks the corneal and patellar reflexes were lost. The pupils were narrow and reacted to light.

On admission were noted subfebrile temperature, slight edema of the legs, moderate facial cyanosis, diffuse râles in the lungs, weak skin reflexes and weak normal plantar reflex, absent abdominal, patellar and Achilles reflexes and hemorrhages in the fundi. Coma set in shortly, with slowed pulse, increased cyanosis and deep, noisy breathing. The patient improved with artificial respiration, but remained drowsy. Lumbar puncture yielded fluid containing considerable blood, which failed to clot. Death followed on the third day after admission to the hospital in coma, with cyanosis and cessation of breathing while the heart remained beating.

The autopsy showed all the fosse at the base of the brain filled with blood. The clots overlay the medulla oblongata, pons and chiasma. The blood was derived from the rupture of a bean-sized aneurysm situated on the mesial side of the right vertebral artery about 0.5 cm. before the junction of the two vertebral arteries.

The earlier literature of vertebral aneurysms is given by Lebert, 1866.⁵ No case like the present

appears to have been recorded, although Gray's "Anatomy," under the heading of "Surgical Anatomy of the Vertebral Arteries," refers to a case of Drs. Ramskill and Bright, in which regnary pain was due to disease of this artery.

Our own case may be classified as irritative. It is probable that the striking attacks of suboccipital pain were brought on by a combination of factors, through pressure of the vertebral aneurysms, aided by heightened intracranial pressure attending the cerebral hemorrhages. The chronic alterations of the cord and posterior root areas were no more marked than the chronic alterations above and below the region of the vertebral aneurysms; yet it is possible that the spinal gliosis found may be related in some way with the attacks. Attention may also be called to the dense pachymeningitis of the posterior cranial fossa. A closer study of non-destructive lesions would be desirable in such cases.

Pain in the back of the neck (*regio nuchæ* of His) is a symptom of some interest. Over and above a number of obvious causes, such as local inflammation of the skin, the muscles and the supportive tissues, cervical caries and osteomyelitis, pachymeningitis, leptomenigitis, neoplasms and various agents of local compression of peripheral nerves of the upper cervical segments, there are a number of obscure conditions of nuchal pain and particularly of pain in the middle of this region (*fovea nuchæ* of His). Special names are often reserved for the fixed or relatively permanent neuralgia of this region, as cervico-occipital neuralgia, occipitodynia. Occipitodynia in a certain context of symptoms is accepted as a sign of neurasthenia. Occipitodynia figures prominently in the well-known diagrams of referred pain in visceral disturbance, often under the caption "spinal irritation."

The search for the particular cause of a given pain is not always as minute as it might be. Pains are, perhaps, too readily classed as functional. The orthopedists occasionally insist on the possible relation of neuralgia to the pressure of dilated or varicose veins upon the regnary nerves. The present case brings out the possibility that arterial disease may effect the same result in one of the favorite sites for functional pain.

The puzzling features of this case of cerebral seizures with coma, ushered in by suboccipital pain, appear to be reasonably accounted for by the post-mortem findings: numerous successive hemorrhages into the silent areas of a cerebrum showing numerous millary aneurysms, and gross aneurysms of both vertebral arteries opposite the junction of bulb and cord.

GUNSHOT WOUNDS OF THE HEAD AND SPINE.*

BY WALTER R. WEISER, M.D., SPRINGFIELD, MASS.,
Surgeon to Mercy Hospital.

J. S., age fifty-three. A robust male, of good family and personal history, was seen Aug. 10, 1904, about fifteen minutes after having received two bullet wounds

of the head. One ball entered the face at the upper surface of the zygoma, on the left side, passing into the mouth through the tonsil, penetrating the wall of the pharynx and lodging in one of the upper cervical vertebrae. The second bullet entered below the zygoma, passed directly through the nasopharynx, and lodged in the masseter muscle of the opposite side. The entire pharynx was much lacerated and the hemorrhage very profuse. The wounds of entrance were small and clean cut and surrounded by powder marks. The greatest amount of bleeding came from a hole, representing the missing tonsil, and undoubtedly from

in his chair at his desk, while his assailant was standing over him and fired diagonally downward with the first shot, and this bullet was beyond doubt the one that penetrated the vertebra. In passing over the malar bone the bullet probably flattened, as is usual where they come into contact with bone, so that, as it plowed out the tonsil, there was great laceration of the soft parts; so also as it again entered the posterior wall of the pharynx there was great injury done before the force was spent upon the vertebra.

UNSHOOT. With Skin. X-Ray.

Tracing No. 1. From skiagraphs.

The route of these bullets is interesting, showing deflection with much laceration of tissue. The wound of entrance of a bullet is always clean cut while that of exit is larger and more lacerated. The victim in this case was sitting

above the right ear, passing through the brain, penetrating the orbit, and completely severing the optic nerve (skiagraph No. 4). Notwithstanding the serious damage inflicted by these bullets, she had practically no elevation of temperature and a pulse fluctuating between 80 and 100.

No attempt was made to remove either bullet until eight weeks after the injury, when the eye began to soften and was removed, together with the bullet and a small piece of the wall of the orbit.

She was delivered at term of a healthy child and, perfectly well, the spine never having troubled her in any way.

CASE V.—Mrs. L. E., aged sixty-four, mother of a victim of the same man as case IV, was admitted to hospital at the same time with bullet wound of skull

of the head. One ball entered the face at the upper surface of the zygoma, on the left side, passing into the mouth through the tonsil, penetrating the wall of the pharynx and lodging in one of the upper cervical vertebrae. The second bullet entered below the zygoma, passed directly through the nasopharynx, and lodged in the masseter muscle of the opposite side. The entire pharynx was much lacerated and the hemorrhage very profuse. The wounds of entrance were small and clean cut and surrounded by powder marks. The greatest amount of bleeding came from a hole, representing the missing tonsil, and undoubtedly from the tonsillar artery. This was controlled by packing. The wound in the posterior pharyngeal wall also bled profusely and this was controlled in a like manner.

When first seen the patient was very thoroughly exsanguinated and in profound shock, but after hemorrhage was checked and hypodermoclysis practiced, he rallied, and the following morning, aside from the inconvenience of the pharyngeal packing, was quite comfortable. After thirty-six hours the packing was removed and there was no recurrence of hemorrhage.

During the first three days following the injury the patient was very comfortable, with a steady decline in the temperature to 99° and pulse to 94. About this time the temperature and pulse gradually elevated, he complained of difficulty in swallowing and was inclined, soon, to keep the head well back. This condition increased until the morning of the ninth day, when he died.

The original plate shows a fracture of the vertebra where the bullet lies (Skiagraph¹ No. 1), and meningitis was produced, no doubt, by infection through the mouth wound.

The second bullet caused a large spot of ecchymosis on the side of the face wherein it lodged and was apparently very near the surface, but was not removed. (Skiagraph No. 4.)

Tracing No. 1. From skiagraph.

The route of these bullets is interesting, showing deflection with much laceration of tissue. The wound of entrance of a bullet is always clean cut while that of exit is larger and more lacerated. The victim in this case was sitting

in his chair at his desk, while his assailant was standing over him and fired diagonally downward with the first shot, and this bullet was beyond doubt the one that penetrated the vertebra. In passing over the malar bone the bullet probably flattened, as is usual where they come into contact with bone, so that, as it plowed out the tonsil, there was great laceration of the soft parts; so also as it again entered the posterior wall of the pharynx there was great injury done before the force was spent upon the vertebra.

The x-ray demonstrated this bullet as lying close to and a little anterior to the vertebra making its removal impractical. During the last day before death, bulbar symptoms developed rapidly, making swallowing almost impossible. There had been a progressive increase of regurgitation through the nares in swallowing for three or four days. Death followed about four hours of coma.

CASE II. B. J., age fifty-five, was a second victim of the same tragedy who came under my care at the same time, and is here mentioned for that reason. The bullet in this case struck the skull a glancing blow, making a scalp wound an inch long, and flattened the tip of the bullet, glancing off to the floor. The victim made a rapid recovery and presented no further symptoms.

CASE III. C. C., age seventy-three, Jan. 2, 1901, while in a fit of despondency, shot himself. One bullet struck the chest wall and was deflected, causing a wound which did not penetrate the chest. The second ball entered the skull just above and posterior to the upper part of the ear and lodged in the cerebellum. I saw him with Dr. W. J. Leonard half an hour after the accident and found him unconscious. On the third day we were able to arouse him and he would answer questions incoherently, always lapsing back to a semi-stupor. He complained bitterly of vertigo, which condition persisted for several weeks. Aside from this and a slight elevation of pulse and temperature, temperature never but once reaching 100°, he showed no symptoms caused by the bullet shown by the skiagraph, Nos. 2 and 3. He is today perfectly well and shows no results of his injuries aside from the scars.

CASE IV. Mrs. J. L., age nineteen, married, and three months pregnant, came into my service at the Mercy Hospital Feb. 11, 1905, one hour after having been twice shot by her husband, one bullet entering the tip of the nose, and, passing directly through the pharynx, entered the posterior wall of the pharynx fracturing one of the transverse processes of the cervical vertebra. The second bullet entered the skull, above the right ear, passing through the brain, penetrating the orbit, and completely severing the optic nerve (Skiagraph No. 4). Notwithstanding the serious damage inflicted by these bullets, she had practically no elevation of temperature and a pulse fluctuating between 80 and 100.

No attempt was made to remove either bullet until eight weeks after the injury, when the eye began to soften and was removed, together with the bullet and a small piece of the wall of the orbit.

She was delivered at term of a healthy child and, perfectly well, the spine never having been affected in any way.

CASE V. Mrs. L. E., aged sixty-two, was the third victim of the same manner as Case IV, was admitted to hospital at the same time with bullet wounds to the

¹ Skiagraphs by Dr. H. W. Van Allen.

The bullet entered through the left parietal bone, was chipped and the three pieces are seen by the skiagraph No. 5 to be imbedded in the brain substance. A second skiagraph which I am unable to produce, because, unfortunately, it has been destroyed, shows that the fragments of the bullet all remained on the left side, or side of entrance, of the brain.

On admission, this patient was in very pronounced shock and was bleeding considerably from the external wound. She had a complete paralysis of the right leg and arm and could not speak. She understood all that was said, but aphasia was complete. She soon fell into a semi-stupor and remained so for ten days, after which she became more active mentally and made an effort to speak, but without success. During the fifth week she said "Yes" and used this word for every answer, realizing that this word was not the one which she intended using. She knew her wants and expressed them by signs, using her left hand. After a few days she was able to add "No" to her vocabulary, and after a few weeks more, a few more simple words; but she had great difficulty in expressing herself, frequently using a word of opposite meaning. This depressed her greatly and after making several unsuccessful attempts to use the proper word, she would burst into tears and grow despondent. During eight weeks there was no control of the bowel or bladder. Involuntary discharges occurred, much to her annoyance. She remained in the hospital ten weeks and since going home has continued to improve in speech, but is learning over again each word that she has been able to use. While vastly improved and perfectly well physically, her vocabulary is still limited. It seems probable that the speech center in this patient was practically destroyed and that she is using the opposite side in her efforts to regain her speech.

Now a brief résumé of the important facts relating to these cases. In Case No. 1, the bullets were located, but it seemed unwise to attempt their removal because of the peculiar position of the important one. The fact that the mouth wound was continuous with the

well and illustrates, with Cases No. 4 and 5, the fact that a bullet wound in the brain substance may cause no serious trouble after the result of the first laceration is over. In Case No. 4, the severe damage inflicted in a pregnant woman without causing further trouble was phenomenal. The bullet still lies close to the spine but gives no trouble so that its removal has not been considered.

In Case No. 5, I believe that the symptoms are not caused by the presence of the bullet fragments, but by the damage to brain substance

Tracing No. 3. From skiagraphs.

inflicted at the time of injury. Removal has not been considered for that reason, and also for the reason that the fragments are widely separated in the brain substance and their removal would be difficult, and in all probability productive of no good.

The wisdom of non-interference in bullet wounds of the brain, where no urgent symptoms are present, is shown, I think, in Cases 3, 4 and 5. The laceration of brain tissue caused by operation and searching for the bullet is usually greater by far than is the damage caused by the bullet, and while I should remove a bullet if located near the surface and in sight I think it wise to practice non-interference in the usual case of gunshot wound of the brain. If symptoms develop which are alarming and the skiagraph can locate the bullet with mathematical accuracy, I should then deem operation a wise procedure. Surely, in Cases 3, 4 and 5, we could not possibly have procured better results by operation than by the treatment followed.

Tracing No. 2. From skiagraphs.

opening through the vertebra and that the bone damage was in the body of the vertebra, in this peculiar location, made us unwilling to interfere. In Case No. 3, although the bullet is shown by the skiagraph Nos. 2 and 3, to be lying in the cerebellum and at first caused pronounced symptoms, the patient is now perfectly

AUTOMOBILES FOR MEDICAL MEN. — From correspondence recently received we gather that it would be useful to draw up a statement of the requirements which an automobile ought to fulfill for the use of medical men, in the country more especially. We shall be very much obliged to correspondents who will send us their views and experiences. — *British Medical Journal*,

The bullet entered through the left parietal bone, chipped and the third No. 5 to be imbedded in the skull. The old skiagraph which unfortunately, it has fragments of the bullet on the side of entrance.

On admission, the patient was in a state of shock and was bleeding from the wound. She had a right arm and could not move it, but that was said, but she fell into a semi-stupor after which she began an effort to speak. In the fifth week she said "I cannot answer, realizing that she intended using. She then by signs, using her hands, she was able to add "a few weeks more, a great difficulty using a word of order, her greatly and after attempts to use the word tears and grow deaf there was no control of voluntary discharges of urine. She remained in the hospital home has continued to improve over again each week. While vastly improved her vocabulary is still in the speech center in the brain destroyed and that she is making efforts to regain her

CEREBRAL EMBOLISM FOLLOWING LIGATION OF THE EXTERNAL CAROTID ARTERY.

BY CHARLES L. ACUDDER, M.D., BOSTON.
Surgeon to the Massachusetts General Hospital

SARCOMA OF THE SUPERIOR MAXILLA. LIGATION OF THE EXTERNAL CAROTID. RESECTION OF THE SUPERIOR MAXILLA. DEATH FROM CEREBRAL EMBOLISM.

S. R. D., a woman, fifty years old, married. Hospital No. 143635. Autopsy No. 1111. Massachusetts General Hospital Records.

The patient had been well. The characteristic was established when she was forty years old. For some years she had had a swelling of the soft parts of the face. Five years ago an operation had been done for the removal of this tumor of the left cheek. Two years ago a swelling of the same cheek appeared and had increased in size gradually. She had slight pain in front of the left ear and at times upon the opposite side of the head. There was a left superior maxillary tumor, hard, firm and apparently extending from the subcutaneous tissues into the bone. The left atrial cavity was dark upon transillumination.

The left external carotid was ligated just below the posterior belly of the digastric before the origin of the facial artery. A complete excision of the upper jaw was then performed. The operation was done in the sitting posture. On the day following the operation a right-sided hemiplegia became evident. Six days later she died, having been partially unconscious from the day following the operation until her death.

REPORT UPON THE SECTION OF THE TUMOR.

Microscopical examination showed that the tumor was composed of a solid mass of small, round cells, having very little protoplasm, lying in a fine fibrous stroma. Throughout the section were large numbers of thin-walled blood vessels. Diagnosis: Small, round-cell sarcoma. Pathological number (57-121).

(Signed) C. C. SIMMONS, M.D.

REPORT OF THE AUTOPSY.

Anatomical Diagnosis: Operation wounds; removal of tumor of the jaw; embolism and thrombosis of the left middle cerebral artery, with infarction involving the basal ganglia, edema pae, arteriosclerosis of the aorta; hypertrophy and dilatation of the heart; cholelithiasis, chronic pelvic peritonitis.

The body of a woman fifty years of age, 160.5 cm. long, well developed, fat.

Trunk.—On the left side of the neck, extending along the posterior border of the sternocleidomastoid, there is a linear wound 9 cm. long, closed with sutures. On section, subcutaneous fat in large amount. Muscle not remarkable. The peritoneal cavity is free from fluid. The peritoneum is smooth and shining. The appendix is not remarkable, except that the distal half rests in a smooth pocket in the peritoneum. The anterior margin of the right lobe of the liver is on finger's breadth above the costal border in the right mamillary line.

Diaphragm.—Right side at third rib, left side at fourth rib. The pleural cavities are free from fluid. The right lung is free. The left lung presents a globose band of fibrous adhesions. The bronchial lymphatic glands are not remarkable. The trachea and bronchi

Autopsy No. 1111. S. R. D. Aug. 7, 1905. Hospital No. 143635.

are free. The lungs, on section, present no areas of consolidation and yield a moderate amount of reddish, frothy fluid.

The pulmonary artery is free. The pericardium is not remarkable. Heart, 398 gm. On section, the myocardium is flabby and pale brown in color. The left ventricle wall measures 11 mm.; the right ventricle wall measures 3 mm. The columnar earner are rather thin. The mitral valve circumference 11.5 cm., the aortic 7.5 cm., the tricuspid, 13.5 cm. The valves, except for their rather large circumferences, are not remarkable. The cavities are rather large. The coronary arteries are free and smooth. The aorta is fairly smooth, presenting in one or two places large, rather soft, fibrous plaques. Liver, 1,284 gm. On section, the tissue is not remarkable. The gall bladder is filled with stones. They are brownish black, firm, and nine of them measure about 1.5 cm. in greatest dimension. The others are numerous and small. The bile ducts are free. The pancreas, on section, is not remarkable. The duct of Wirsung is free. Spleen, 187 gm. The organ is not remarkable. Adrenal, normal.

Kidneys: Combined, 320 gm. Capsule strip, leaving a smooth surface. On section, the tissue is fairly firm, the markings are retained and the cortex measures 3 to 5 mm. The section surface is pale. Ureters free.

The bladder, on section, is not remarkable. The uterus and adnexa, on section, are not remarkable, except for the presence in each side of fibrous adhesions which bind the ovaries and distal portions of the tubes together. The stomach and intestines, on section, present no lesions.

Head: On the left side of the face, in the region of the left half of the superior maxilla, there is a wound which extends from the malar bone over towards the nose, then down along the nose to the region of the median line of the upper lip. The wound is closed with sutures.

On section, the pia is infiltrated with a moderate amount of pale fluid. The sinuses are free and the middle ears are normal. The brain weighs 1,225 gm. On section, the ventricles are free. The internal carotids are free. The vessels leading to the right half of the brain are not remarkable. The vessels leading to the left half of the brain, with the exception of the middle cerebral, are not remarkable. The left middle cerebral, a short distance from its origin, is distinctly occluded by a firm, gray red, thrombus-like mass. In some of the first branches of the middle cerebral the thrombus mass is apparently prolonged as a black red, somewhat softer material. In the situation of the basal ganglia on the left there is a pale, opaque, grayish red, disorganized, more or less disintegrated soft mass of brain tissue, which extends from the posterior portion of the left frontal lobe back as far as the posterior portion of the left thalamus, and including a portion of the thalamus laterally, and to the left and as above a good half of the striate body and extending downward into the temporal lobe. The condition extends into the left temporal lobe over quite an area and reaches as far as the cortical portion. In this situation the brain tissue is pale, disorganized and thin. The brain tissue elsewhere is not remarkable. There was no evidence of arteriosclerosis in the cerebral vessels.

Pathological report: Embolism of the left middle cerebral artery. No growth. Liver: No growth. Spleen: No growth.

(Signed) Charles L. Acudder, M.D.

Pathological Assistant

Massachusetts General Hospital

The facts of especial interest in this case are that whereas the preliminary ligation of the external carotid was attended with no difficulty at the time, was quickly accomplished and prevented undue hemorrhage while excising the jaw yet subsequently a clot became dislodged and was carried by the internal carotid into one of the cerebral arteries causing signs of partial unconsciousness and hemiplegia upon the opposite side, and death.

The drawings here shown illustrate well the extent and the gross appearances of the lesion. This deplorable outcome is to be considered as possible in the ligation of the external carotid, although it is comparatively rare. Matas has recorded in his own experience 3 deaths from cerebral embolism following 68 ligations of the external carotid.

Personally, I do not believe that preliminary ligation of the external carotid is always necessary in excision of the upper jaw. In this particular instance the feebleness of the individual led me to take this precaution against hemorrhage.

Medical Progress.

PROGRESS IN PATHOLOGY.

[BY JOSEPH H. PRATT, M.D., BOSTON.]

CLINICAL BACTERIOLOGY OF TYPHOID FEVER.

BRION and Kayser¹ have studied, clinically and bacteriologically, in the laboratory of Professor Forster and in the university hospital of Professor von Krehl, over two hundred cases of typhoid fever during the past two years. The abundance of material was a consequence of the strong effort Strasburg is making to stamp out the disease. No less than 96% of all the typhoid cases registered in that city were treated in the typhoid department of the medical clinic. Agglutination tests were made at a dilution of 1:50 and 1:100 with *Bacterium typhi*, and at the same time in a dilution of 1:100 with *Bacterium paratyphi A* and *Bacterium paratyphi B*. Both the microscopic and macroscopic methods of performing the tests were employed. Cultures of dead bacilli were not used, as in several cases the agglutination test was positive with young, living cultures while it failed with dead cultures of the same strain. In performing the test the tubes were kept at least three hours in the incubator at 37° C. The test was not regarded as negative unless no clumping occurred after the tubes had stood an additional half day at room temperature. The microscopic agglutination occurred often in considerably higher dilution than the macroscopic. The earliest positive Gruber-Widal reaction was obtained on the third day. This occurred in three cases. In typhoid fever or paratyphoid fever the agglutination failed in only 5% of the cases. In 10% of the cases *Bacterium paratyphi A* was agglutinated as well as the real typhoid bacillus, although cul-

tures from the blood yielded pure growths of *Bacterium typhi*. A group agglutination with *Bacterium paratyphi B* occurred in 8% of the cases. About 1% of the sera agglutinated the causative bacterium in lower dilution than it did one or more of the related organisms. The recognition of the infecting organism by the agglutination power alone can be done more often with the microscopic than the macroscopic test. Additional aids are the "delayed macroscopic agglutination" and Castellani's experiment. The power of agglutination can vary greatly from day to day. Hence, the agglutination tests should be repeated at least once a week. Their experience showed that it is extremely rare for affections other than typhoid to give the Gruber-Widal test with typhoid bacilli in dilution of 1:100. The diagnostic value of blood cultures was strongly emphasized by this study. In the first week of the disease the typhoid bacillus was cultivated in the blood from 94% of the cases. Beginning with the second week the number of successful blood cultures diminished. The cultural medium chiefly employed was sterilized ox bile. To 5 cc. of bile 2.5 cc. of blood were added. The tubes were kept twelve to twenty-four hours in the incubator, then transplantations were made to Endo's fuchsin plates. The number of positive stool cultures increased from the first to the third week of the disease. In about 25% of the cases examined during the febrile period bacilli were found in the urine. On the fifteenth day of convalescence the feces and urine were found free from typhoid bacilli in 93% of the cases. Typhoid nephritis occurred without the presence of typhoid bacilli in the urine. Three of the two hundred patients were chronic "typhoid-bacillus carriers." Occasionally when agglutination and culture tests were negative Pfeiffer's reaction or the test-tube bactericidal experiment gave the etiological diagnosis.

Among 200 clinical typhoid cases 2 (or 1%) were instances of infection with *Bacterium paratyphi A*, and 7 (or 4½%) with *Bacterium paratyphi B*. Paratyphoid exhibits the same clinical features as typhoid fever. At the autopsy of a fatal case of paratyphoid fever the classical intestinal lesions of typhoid fever were found in the lower ileum and the colon. The clinical diagnosis was typhus gravissimus. There was irregular fever with a maximum temperature of 40° C.; marked delirium; rose spots; meteorismus; stools infrequent but of pea soup consistence. Exitus occurred in the third week of the disease. On the sixth day of the disease *Bacterium paratyphi B* was isolated from the blood. On the tenth day agglutination was positive with *Bacterium paratyphi* in a dilution of 1:100, and only with this bacillus. At the section the mesenteric lymph nodes were found enlarged. In the ileum were a number of ulcers with sloughs involving Peyer's patches. In the cecum, colon ascendens, and lower part of the flex. sigmoidea were deep ulcers involving the muscular coat. The spleen was not enlarged. *Bacterium paratyphi B* was isolated from the heart's

¹ Deutsches Archiv für klinische Medizin, 1906, lxxv, p. 525.

blood, bile, spleen, mesenteric lymph glands and cerebrospinal fluid. None of the cultures made at autopsy yielded a growth of typhoid bacillus.

Terburgh² examined the canal water of Amsterdam, bacteriologically, employing the v. Drigalski-Conradi plate medium combined with the caffeine-enriching method of Hoffmann and Fischer. Sixty-one pure cultures were obtained. Eighteen formed red colonies on the plates. Sixteen of these belonged to the colon group. The remaining forty-three micro-organisms grew upon the plates as blue colonies. Two were spirilla, nine were cocci, the remainder were bacilli. Three of these colored Petruschky's litmus milk blue in twenty-four hours, and fermented glucose with the formation of gas. They formed no indol. On potato they yielded a yellow growth. The red color in litmus milk was still present after twenty days, while in typhoid and paratyphoid litmus milk cultures the blue color had returned within twenty days. The organisms of this group were not agglutinated by typhoid immune serum in a dilution of 1:10. Fourteen of the cultures that formed blue colonies in the v. Drigalski-Conradi plates belonged to the group of *Bacillus fecalis* alcaligenes. Some yielded an abundant growth in bouillon, others produced only a slight clouding. Only three formed a surface pellicle in bouillon. Similar differences in growth were observed on potato and other media. Only one of the races was agglutinated by typhoid serum and then only in a dilution of 1:5.

Uncoagulated blood has very slight bactericidal power. Lubarsch found that 1 cc. of the blood serum of a normal rabbit would destroy about 30,000 anthrax bacilli in vitro while even 600 of the micro-organisms injected intravenously brought about the death of the animal within two days. Conradi made somewhat similar observations. The extravascular blood serum of a typhoid patient had a marked bactericidal action against typhoid bacilli, although the circulating blood of the patient at the time contained about 200 typhoid bacilli per 10 cc.

Bile checks coagulation and does not interfere with the growth of typhoid bacilli. For cultivating the micro-organisms Conradi³ used ox bile to which 10% of peptone and 10% of glycerine were added. Blood was obtained from the ears of typhoid patients. Usually $\frac{1}{2}$ to 2 cc. of blood was obtained without discomfort by cutting the lobe of the ear with a lancet. After the tubes were kept sixteen hours in the incubatory, Drigalski-Conradi plates were inoculated. He isolated the typhoid bacillus twenty-two times by this method, and six times paratyphoid bacilli. He obtained negative results in about 50% of his examinations. The typhoid bacillus was found in the blood in mild cases and in convalescent patients who were free from fever. The use of blood from the ear is not advocated, if permission can be obtained to withdraw

blood by means of a syringe from the vena mediana.

Different strains of typhoid bacilli vary greatly in their agglutinating power. It was formerly thought that the more virulent the strain the less readily was it agglutinated. Eisenberg and Volk, as well as Wassermann have shown that the agglutination is a more complex phenomenon than at first appeared. Cole⁴ found that a serum which agglutinated one race of *Bacillus typhosus* in a dilution of 1:8000 failed to agglutinate another race in dilutions above 1:1000. He showed that this was due to differences in the bacilli and not in the sera by inoculating rabbits with races of *Bacillus typhosus* that had been agglutinated with difficulty. The serum agglutinated other races in higher dilution than it did the race against which it had been immunized. The experiments showed that the variations in agglutinating power were due to differences in the agglutinable substance and not to the agglutinin. The agglutinable substance as well as the agglutinin is composed of a haptophore group and a functioning group. To immune serum bacilli of one race were added. After standing an hour the tubes were centrifugalized, and then the agglutinating power of the clear fluid was tested with different strains of *B. typhosus*. It was found that the greater power of agglutination possessed by some strains of *B. typhosus* is associated with greater power of combining with agglutinin. Difficulty in agglutination is associated with a diminution in the number of receptors.

Falta and Nieggerthal⁵ have made a study of the variations in a number of races of typhoid bacilli. They show that individuals can react differently to the same species of typhoid bacilli. Individuals react differently to different races of typhoid bacilli. The agglutinating power of serum as well as the agglutinability of the typhoid bacillus are, therefore, not absolute but relative terms. The writers' interest in the subject was stimulated by a small epidemic of typhoid fever which occurred in a suburb of Basel. A number of the patients were admitted to Hiss's clinic. The first case offered considerable difficulty in diagnosis. The clinical picture was not distinct, and the serum failed to agglutinate either of the two races of typhoid bacilli in the hospital laboratory during a period of seven weeks after his admission (the first ten weeks of the disease). Later, another patient from the same village was received who exhibited all the clinical signs of severe typhoid fever. His serum also failed to agglutinate the laboratory races during the first six weeks of the disease. Paratyphoid bacilli A and B were likewise not agglutinated. The spleen was punctured and a bacillus isolated which had all the characteristics of a true typhoid bacillus. This organism was agglutinated by the blood of the two patients in as high dilution as 1:160. Agglutination tests made at the same time with the laboratory

¹Cent. für Bakt., Erste Abt., Orig., 1905, xl, p. 258.

⁴Deutsches Archiv für klinische Medizin, 1906, lxxv, p. 120.

stocks were all negative. Five different races of typhoid bacilli were obtained from different parts of Germany. Two of these were agglutinated in rather high dilution. The blood from a number of cases in the same epidemic exhibited a graduated scale in the agglutinability of these typhoid races. For example, the serum from the second case in the fifth week of the disease agglutinated the organism isolated from its own blood in the dilution of 1:160; Casperi, 1:320; Königsberg, 1:80; Frankfurt, 1:40; Berlin, 1:20; Prague, 1:20. Late in the disease the blood of all the patients agglutinated all the races of typhoid bacilli. The blood of the first patient did not give a positive reaction with one of the stock typhoids until the tenth week of the disease. A positive result was then obtained in the dilution of 1:40. They found no race of typhoid bacilli which, under all circumstances, was difficult to agglutinate. The agglutinating power of a serum is the resultant of three factors: the receptor-apparatus of the immunizing or disease-producing race, of the race used for the agglutination test, and finally of the serum of the infected individual.

After the sera of some of the patients acquired the power of agglutinating the different races of typhoid bacilli a Hemmungsreihe appeared. They apply this term to the paradoxical property of a serum whereby a concentrated serum does not agglutinate, while the same serum diluted produces agglutination. This interesting phenomenon was first described by Eisenberg and Volk, and has subsequently been studied by Schiga, Schwoner, Lipstein, Lipschütz, Volk and de Waele. These authors hold that there are substances in the serum which have a greater avidity for the bacteria than the agglutinins. These substances attach themselves to the receptors of the bacteria, and hinder the anchoring of the active serum agglutinins. As these inhibiting bodies are present in smaller numbers than the agglutinins, by increasing the dilution of the serum the concentration is so much lessened that they can no longer interfere with the activity of the agglutinins. The writers hold that these bodies may be derived from Joos's thermostable agglutinins. For the cases with absolute lack of the inhibition bodies they advance the theory that in these individuals no labile agglutinins have been produced. In certain cases in man and infected animals the inhibition bodies were absent throughout the entire course of the disease. In a number of cases the inhibition bodies were completely absent in the beginning of the disease, and appeared later in its course, or they were present at the first examination and increased during the progress of the disease. In a number of cases inhibition zones suddenly developed. This was associated with the development of complications. For example, the blood of one patient on the tenth week of the disease agglutinated typhoid Basel 1:80; the following week croupous pneumonia developed, and this agglutinating power was lost in all dilutions. In a single

serum inhibition bodies may be present for one or several races of typhoid bacilli, while they are completely lacking for other races. The frequent presence of inhibition bodies in typhoid sera furnishes additional ground for making a series of agglutination tests with serum of various dilutions. Cases of typhoid fever in which the Gruber-Widal reaction develops late in the disease or not at all, are explained by the fact that the typhoid races used for the test are not readily agglutinated by that particular serum. This source of error can be removed by using a number of different races of typhoid bacilli. They recommend the employment of mixed bouillon cultures in the laboratory. In addition to the several typhoid races it would be well to inoculate the culture with the two types of paratyphoid bacilli. The difference in the relative agglutinability of the different typhoid races occurs chiefly in the sera with low agglutinating power. With increase of the agglutinating power the difference usually disappears.

Porcile⁶ studied seven strains of typhoid bacilli and found that they were agglutinated in equally high dilutions by every typhoid serum tested. Paratyphoid and colon bacilli, as well as all other related bacteria, were only agglutinated by the different typhoid sera in low dilutions. In order to distinguish different varieties of bacteria by the serum test it is necessary to employ sera of very great agglutinative power. This paper is based entirely upon experimental work. Rabbits were inoculated intravenously with dead cultures and the agglutinating power of the sera tested. The macroscopic method of performing the Gruber-Widal test was employed.

Grünberg and Rolly⁷ found there was no relation between the height of agglutination and the number of typhoid bacilli in the circulating blood. Neither the agglutinating power or the number of micro-organisms in the blood has any definite relation to the severity of the case. In 70% of the cases the typhoid serum agglutinated the paratyphoid bacilli as well as the typhoid bacillus. In 35% of forty cases agglutination of the paratyphoid bacilli occurred in higher dilution than that of the typhoid bacillus. The blood cultures in these cases yielded pure growths of *B. typhosus*. Hence they were dealing with group agglutinations "Mitagglutinationen" and not with mixed infections.

Often the serum of a typhoid patient would agglutinate one species of paratyphoid and not the other. In 55% of the cases the blood agglutinated *B. coli* and in 100% *B. enteritidis* Gärtner.

Typhoid bacilli were isolated from the blood in thirty-two (80%) of the forty cases of typhoid fever examined.

Manteufel⁸ reports from Eberth's laboratory that with eighty-five positive Gruber-Widal tests there was an agglutination of paratyphoid bacilli in fifty-eight, or 68%. He never found the paratyphoid bacillus in infections due to Eberth's

bacillus, agglutinated in higher dilution than the typhoid bacillus. This is opposed to the claim of Grünberg and Rolly but is in support of the observation of Korte and Steinberg.

Reports of Societies.

NEW ENGLAND ASSOCIATION FOR THE EDUCATION OF NURSES.*

DISCUSSION ON COMPENSATION FOR UNDERGRADUATE NURSES.

THE PRESIDENT, DR. R. C. CANNON: I have one confession to make, and that is, I have seen clearly the error of my ways in regard to this matter. In a public address made some years ago, I stated that I thought it was an anomaly that nurses paid nothing for their training. But now I see that nurses do pay for their training always—they pay in labor, they pay in service, and that argument cannot be used. One may say that nurses ought to pay more, that they ought to pay in money as well as labor, but one cannot say that the nurses in most training schools do not pay for what they get.

In discussing the question of compensation, I think it most important that we should hear from representatives of all training schools which have tried, or are now trying, to give up paying nurses. I will call upon them.

MISS DORTCHER, Massachusetts General Hospital: When the preparatory course offered by the trustees of Simmons College was offered to our school, it was decided to do away with the money allowance which had already been decreased from \$11 to \$10 a month. It was decided to do away with this allowance and to charge \$50 and to require a deposit of \$10 to cover breakage. In the first class received for a preparatory course there were 8 students. The class, by the way, was limited to 20, but we were unable to get more than 8 students. The second class, which entered in February, numbered 11, and the third, which entered in September, 14 students. That was not nearly enough to carry on the work of the hospital, and in September of this year we were obliged to go back to our former method of offering an allowance, that is, \$6 a month for the three years' training. While the better education which was offered appealed to a great many, there were also a great number of young women who were unable to enter the school for three years if no money was paid. The trustees offered four scholarships, but we had just one application.

THE PALMER, Framingham, Mass.: For the first years of our school we paid a salary of \$8 for the first year, \$10 for the second, and \$12 for the third year. Two years ago we abolished all pay for our nurses. We had some difficulty in getting nurses that we did not have when we paid them, but there is this to be said about the change, that the quality of nurses that we get is better than under the first plan. They are better prepared and come with the hope of a first-rate education. I should not say, perhaps, that they give us better service. We have also resorted to the plan of advertising for pupils, and the standard of training has been higher in the new regime, and we are very much pleased. Our present senior class still received the money that was promised them when they came into the school, but the last two classes that have come in have received no pay.

THE PRESIDENT: Does the Framingham school provide uniforms and textbooks for its pupils?

MISS STEWART, Superintendent of Nurses at the Framingham Training School: Yes.

PRESIDENT: A hospital which gives uniforms, etc., does not seem to be on a non-paying basis.

MISS KIMBALL, for the New England Hospital, Boston: When the New England Hospital's training school was established, the course was one year; then it was increased to two years and now it is three years. Two years ago we adopted the system of non-payment. We have not had so many applications, but we have enough to keep the school running. Uniforms are supplied at the hospital.

DR. WORCESTER, Waltham, Mass.: When the Waltham school was started, twenty-one years ago, we paid \$8, \$10, and \$12 a month to our student nurses. I do not know just when that allowance was finally taken away. It went through several stages of reduction, and certainly as long as ten years ago, the custom of paying anything to the probation and student nurses was done away with. Then about eight years ago the school decided no longer to furnish uniforms or textbooks, or any materials, and four years ago the school decided to charge a tuition fee. At first a small fee was charged and then a larger. Now the school charges \$250 for its first year and \$100 for its second year. Our experience with the tuition fees, being more recent, is more fresh in my mind. There are now three classes in the school, some of whom are paying their tuition fees. Of the first class, only 3 out of the 21 paid; in the second class, 11 out of 25 or 26 paid their tuition fees, and out of the present class, 20 of the 28 pay. There are working scholarships, as they are termed, so that a student nurse, by giving six months of extra service is relieved of paying any tuition, taking two vacations out of the four years' course; a paying probationer will give forty months of service and pay in all \$350 tuition fees, paying, of course, for uniforms, textbooks, and all such materials, and a nurse who comes in on a working scholarship will pay no tuition fees, but she will give forty-six months of service. We have only three classes who are paying their tuition fees, and we are not quite yet clear of the old regime.

MISS BIRNOS, for the Cambridge Training School: The school has just opened this fall, and the first class comprises only seven students, all of whom are paying a tuition fee. The first year's tuition is \$150, and in each of the remaining years \$75. All of the student nurses now in the school expect to have a four years' course. The students pay for their uniforms, books, etc.

DR. BARNY, for the Cambridge Hospital: The hospital and training school are two entirely different institutions; the hospital has no training school. The school of which Miss Briggs speaks opened this fall.

MISS KIMBALL, New England Hospital, Boston: I also should say that the quality of our nurses has improved, and in one case there has been a considerable increase in the number of nurses.

DR. WORCESTER: I would like to ask Miss Dorrcher why the scholarships were not applied for.

MISS DORTCHER: I think probably the women did not understand the nature of the scholarship. The application was being accepted when we made a mistake in the school.

DR. WORCESTER: I would like to say a word. I wish the lady who spoke for the New England Hospital might be reminded of the admission she was making. One committee who took charge of the training schools for nurses in America, Miss Kimball.

THE PRESIDENT: I would like to say a word in regard to the preparation of nurses. Most of the training schools are doing something in money. Of course, we cannot have a school which is not on a non-paying basis.

* Report of the Third Semi-annual Meeting.

such as they may need, and most of them pay something in money. I think that it will be found to be a necessity. The Massachusetts General Hospital tried to give up paying and it failed to work. The schools who have made a success of it are those where it does not make any difference whether they have twenty or twenty-five nurses. But in a large charity hospital the number of nurses must be kept up, and those hospitals cannot afford to pay \$21 a week for graduate nurses unless they can get it back from the patients. A large number of young women would find it impossible to take any training were they not paid in money, and some of the best nurses are in that lot. I do not see how we are to keep from paying a small amount. I think most training schools have had some difficulty in getting a proper number of nurses to fill their nursing staff, and I am quite sure that a small sum of money must be paid, say \$6, \$7 or \$8. The McLean has reduced the amount of compensation. Formerly it paid \$14 a month; now it pays \$7 and \$10. We have to pay more for the men, otherwise we cannot get the type of applicant which is needed for a hospital of a special sort. There must be a large number of men nurses employed. Our safety and salvation is to teach them. There is no other way to get what we want, and we pay to get those men. We have to pay them just what we used to, and I suppose we shall have to continue to pay them.

MISS DOLLIVER: I know that the system of not paying nurses has been successful in Johns Hopkins and in the New York hospitals, where the number of nurses must be kept up. I think in New England there are too many hospitals.

DR. TUTTLE: I think it might work once in a while, but not in a large number of hospitals.

DR. WORCESTER: I am sorry that Dr. Tuttle is possessed of so little faith. I should think he could read the handwriting on the wall. What does a little miserable \$6 amount to? I believe that a great many young women are deterred from going into a profession where all payment is made in labor. There are families who would rather pay a fee and have their daughters get longer vacations and shorter hours than have them work it all out. Our experience at Waltham can hardly be placed side by side with the large and famous hospitals, but we now find that when the option is given of payment in part in money and with longer vacations, families are anxious to take that alternative. It seems to me that it is fairly conceded that the nurse in the larger hospital pays for her training in work. Look at the Boston Lying-in Hospital; considerable of the work is done by the men who go there to obtain their education as obstetricians. In my time we were not even given our board there, and, moreover, we were compelled to pay a fee for the chance to go there, day or night. Are not nurses hungry for that training in obstetric nursing? Of course they are. Why, the Massachusetts General Hospital has to send its nurses on to New York for this training! Nurses would be willing to go into such a hospital as the Lying-in Hospital and to pay a small fee for the privilege.

MISS DOLLIVER: I have told what our experience has been, and although that little \$6 a month does seem small, you can see it makes a great difference to the woman who hasn't got it. [Applause.] We tried that thing very hard. We were paying the teachers, we were doing all we could for the pupils when we got them there, but we could not get them. I do not think that the nurses we got were distinctly better than those we got before. I think if we ever get on to a non-paying basis, it has got to be very slowly. We advertised very widely and in many ways tried to get

nurses, but we could not get them until we offered our \$6 a month again.

PRESIDENT: One point that I think is sure to come out if this change ever does come about, and we have nurses paying tuition; that is, that the nurse will have a very different standing in the hospitals. Then the nurse will be on the same basis as the medical student. How the hospitals will like that I do not know; but I feel sure that this change cannot be made, if it is ever made, without changing the basis of the pupil nurse in the hospital.

DR. TUTTLE: It has been said that the compensation is going down. It had to, as you can see, when you consider the number of attendants that have to be employed to take care of the patients.

MISS WALLACE: Is not an insane hospital on rather a different basis than a general hospital? These pupils do not have the same opportunity for private nursing as the nurses in a general hospital.

DR. HUGH CABOT: I think that the discussion is being carried on under somewhat of a misunderstanding. It seems to have been generally assumed that we are all talking about the same class of nurses, — perhaps I might say the same type of nurses, — and I do not think that this is a sound assumption. The nurses with whom Dr. Worcester is dealing and those whom they have at Johns Hopkins are, I think, drawn from a distinctly different class of population from most of the nurses to whom we have been paying a compensation at the Massachusetts Hospital, for instance. There are a considerable number of women interested in nursing and desirous of being trained as nurses, who have not, however, any considerable intention of continuing the practice of nursing as a means of livelihood. A certain number of them have always been found at the Massachusetts Hospital, and I have been interested in following the careers of some ten of them who came under my personal observation. They were women who did not need the small compensation which was given them and could very well have paid handsomely for their training. None of them remained eighteen months in the profession and none of them have left because they married. In a word, I am doubtful whether the average woman who can afford to pay handsomely for her training is likely to be a great addition to the profession of nursing. They are not the stuff of which good nurses are made. It is probably an excellent thing that provision should be made for training dilettantes in nursing, but we must not delude ourselves with the idea that these nurses are to be the bone and sinew of the profession, for they will, as a rule, drift into other fields and acquire fresh interests. Those to whom compensation is a necessity will, I believe, continue in the future as in the past, to furnish the majority of nurses to whom we must look when we need to have real work done. It may well be that from the other class we may draw women willing to devote much time to their training and be in the end, competent to assume executive positions. Such women will need a broader training than any one institution can now give them and they would benefit much by an opportunity to study under various systems and different teachers.

MRS. H. L. BURRELL: I am not one who ever thought that nurses did not pay for their training. I *always* thought they paid well for their training, and I particularly think so to-night, when I see on the last chart how much money the nurses bring to the hospitals during their training. I think it is practical for nurses to pay in money for their training only up to a certain point, for they must have long-continued care of the patients in order to get their training, and this care is of great money value to the hospital. The point I

wish to make here is that a nurse cannot be trained in nursing without actually doing the work, which is of great money value to the hospital. The only part she could justly pay for in money would be supplementary work like the training given at Simmons College. Some say that if they are to be paid you are putting the profession on a commercial basis. If you are going to put it on a commercial basis, you cannot talk about \$14 a month. Of course, we do not want to put it on a commercial basis, but what we do want is to place the nurse in a position where she can do good work without worrying about the debt or the drag upon her family, and without fearing that when she comes out she must face a debt and be tired besides. You cannot get your best work under these conditions. I think it is economy to pay the nurse so that her mind will be free.

THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION

EIGHTEENTH ANNUAL MEETING, HELD IN LOUISVILLE, KY., DEC. 12, 13 AND 14, 1905.

(Continued from No. 11, p. 300.)

COMMON DUCT OBSTRUCTION.

DR. J. WESLEY LONG, of Cincinnati, N. C., stated that, as compared with gall-stones in the gall bladder, the condition was many times more serious. He quoted the as yet unpublished statistics of the Mayo clinic, where there had been more gall-stone operations done than in any other clinic in the world, showing that in simple gall-stones in the gall bladder, the mortality of operation was less than one-half of one per cent, while the mortality in operations for common duct obstruction ranged from 11.9 per cent in benign cases to 40 per cent in malignant cases. These facts were brought out to emphasize the prophylactic value of operating while the stones were yet in the gall bladder.

Touching the etiology of common duct obstruction, he took the position that practically all cases were due either to stones or to malignant growths which themselves were caused by the irritating presence of stones. Gallstones might exist in the gall bladder for a long while without producing symptoms, but once in the common duct, not only pronounced symptoms, but many serious complications arose. The mortality in these cases was due to the complications, the cholelithiasis, infection, inflammation and exhaustion due to hemorrhage at the operation. He emphasized the fact that common duct obstruction could be treated only by surgical methods. After removal of the obstruction, the first consideration was drainage, since it was imperative to overcome the infection, and, second, that no operation must be deemed finished until the patency of the opening into the duodenum was assured.

Attention was called to the importance of not removing the gall bladder in the operation of cholecystectomy, since stones occasionally reformed in the common duct and in these cases the gall bladder served for drainage.

A number of cases of operation for common duct obstruction occurring in the hands of Dr. Long were reported, showing the profound disturbance caused by the stones, and the great relief afforded by their removal. In one case it was noted that the stones had ulcerated through the side of the gall bladder and into the common duct—an exceedingly rare occurrence.

GANGRENE OF THE GALL BLADDER, RUPTURE OF THE COMMON DUCT. A NEW SIGN.

DR. JOSEPH RANSOHOFF, of Cincinnati, Ohio, reported a case of gangrene of the gall bladder, in a male patient, aged twenty-one, with recovery following operation.

The second case was one of rupture of the common duct with an unusual sign. Operation was done, followed by recovery of the patient.

Although the cases differed in many important points they had enough factors in common to warrant their consideration together. In each of them a rapidly developing peritonitis made an operation imperative as a vital indication. In each the operation revealed a condition which to the naked eye at least had all the earmarks of a peritonitis, which might speedily cause death. In one there was an unruptured but gangrenous gall bladder, the contents of which were proved to be sterile; in the other there were large quantities of free bile in the peritoneum.

He called attention to a sign which was noticed in the case of ruptured duct before the incision was made, and one to which he believed attention had not been directed. It was a localized jaundice of the umbilicus. Although a single case was not usually sufficient to warrant the assumption that something new had been observed, this feature was so marked that he could not refrain from believing that further observation would give to this localized jaundice some value as a sign of free bile in the peritoneal cavity. In the case presented, this feature gained an interest as the staining of the subperitoneal fat with bile was observed in the incision through the abdominal wall. The jaundice was doubtless purely the result of imbibition. It made itself manifest first in the integument of the navel, because this part was thinner than the rest of the abdominal wall.

Total gangrene of the gall bladder had, to his knowledge, not been observed except in the case presented as an affection independent of gallstones. Total gangrene of the gall bladder is rare. In the case reported a most careful search failed to reveal the presence of a stone.

EXPERIENCE WITH DOWNES' ELECTRO-THERMIC ANGIOTRIPE IN PELVIC AND ABDOMINAL SURGERY.

DR. J. WESLEY BOYCE, of Washington, D. C., had employed these angiotripes in 203 abdominal and 27 vaginal operations. These 230 operations had been hysterectomies and panhysterectomies, and the removal of the appendages by the vaginal route, removal of the same structures by the abdominal route, removal of the vermiform appendix, the spleen, the kidney, of parovarian cyst, of portions of the intestines, etc.

The instruments were described in detail; also the technique of application.

In these 230 cases he had two of hemorrhage subsequent to operation. He could not believe the method of hemostasis employed was responsible in either instance. In the first abdominal panhysterectomy was done for severe suppurative inflammation of the appendages of a very feeble and emaciated woman. Three weeks later, after being allowed to walk about for two days, she was seized with hemorrhage from the bowels, stomach and vagina. A mass was touched in the pelvis; her temperature became elevated, as was the pulse rate. The hemorrhage continued for ten days for two weeks without improvement, and then the abdomen was reopened without any form of coagulation, even local being refused by the patient. A large amount of blood coagula was removed from the peritoneal cavity, vagina and abdominal through-out.

through rubber tube drainage installed, and thorough irrigation of the peritoneal cavity, with salt solution, was done after separation of multiform adhesions. Later feces and urine escaped by both ends of the drainage tract. Persistent irrigation and feeding cured her malady and she is a robust woman to-day.

In another, two weeks after vaginal hysterectomy for fibromata, the patient had a sharp vaginal hemorrhage after walking a little more than on previous days. An examination with a Sims speculum revealed a malodorous discharge from the left lateral fornix of the roof of the vagina. The temperature was elevated about one degree. Daily irrigation for a week ended the trouble. In both cases he was confident latent mild infection was responsible for the hemorrhage.

In no other instance had hemorrhage occurred, and he had the simplest and most perfect faith in the hemostatic properties of the instrument.

The advantages of the electro-thermic angiostyle of Downes in pelvic and abdominal surgery seemed to be a more reliable hemostasis than by ligation; freedom from hemorrhage during operation; the ease of its application in locations in which the use of ligatures would be very difficult and uncertain; the greater security against dissemination in radical operations for malignant disease; the ability to sterilize unclean areas before suturing, as in intestinal and appendiceal surgery; lessening of the tendency to the formation of post-operative adhesions; the increased speed in operations, such as removal of the uterus, the appendages, or the vermiform appendix, and the greatly lessened amount of pain following operation.

The disadvantages were the danger of accidental injury of the bladder, rectum and ureter; the necessity of great precision in its employment, and the special care necessary to keep the paraphernalia in good working condition.

DISCUSSION.

DR. ANDREW J. DOWNES, of Philadelphia, Pa., in speaking of his instruments, stated that for four years he had not used a ligature except in the case of a woman upon whom he operated for extra-uterine pregnancy, and who was moribund at the time. He had performed intestinal anastomoses and gastro-enterostomies with his instruments; other surgeons had removed gall bladders, kidneys, etc. Personally, he had done four or five hundred hysterectomies with them, while other surgeons had performed from sixty to seventy hysterectomies with them.

He did not think hemorrhage in the two cases reported by Dr. Bovee could be attributed to the use of his method.

DR. CHARLES P. NOBLE, of Philadelphia, had used the Downes instruments a number of times in cases of removal of the uterus for cancer, and said they were a great advance in this operation. They possessed a number of advantages over the application of the ligature. The chief advantage of the clamps over the ligature was that after the uterine arteries were tied on each side, when one came down to the vaginal plexus, which was the most troublesome part of the operation when using the ligature, the veins were apt to leak and flood the field, requiring a number of ligatures to secure hemostasis around the cut vagina. If these instruments were used, the field would be perfectly dry. There was no trouble from hemorrhage.

From the standpoint of recurrence of cancer, the instruments had not been used long enough to give figures as to results; but one could believe from the work of Byrne that much better results could be obtained with the aid of these instruments than with ligatures, etc.

DR. HOWARD A. KELLY, of Baltimore, said he saw Koith, of Edinburgh, in 1887, remove an ovarian tumor with Skene's instruments; but those instruments were not satisfactory, and when Dr. Downes brought out his instruments he procured a set of them and had found them satisfactory, with the exception that he had not been able as yet to install a satisfactory plant in the Johns Hopkins Hospital for their use.

While the Downes instruments were practical and useful in surgical work, he thought if surgeons exercised more care as to the character of ligatures they used daily, it would limit the use of the Downes method of instrumentation. He referred to the importance of using fine silk ligatures which controlled bleeding from large blood vessels and were practically innocuous.

OPERATION FOR LARGE RECTOCELE.

DR. GEORGE H. NOBLE, of Atlanta, Ga., presented the technique of an operation which was intended only for large rectocele. Small rectocele was relieved by the ordinary perineal operations. In large rectocele not infrequently there was more or less tediousness, loss of blood in the denudation and certain objections to puckering the overstretched and distended tissues together and forcing them into the rectum. Furthermore, there were unsatisfactory results by infecting the strong and resisting recto-vaginal septum. This operation was presented for the purpose of overcoming those objections. In the technique it would be observed that the rectocele is actually resected and that the strong or normal recto-vaginal septum above the weak occluding point is drawn down to the level of the levator ani muscle and securely anchored.

(1) A thorough dilatation of the anus and recleansing of the rectum. (2) Denudation of a wide collar, as it were, the ring around the neck of the rectocele, beginning high up in the vagina and extending near to the promontory of the rectocele. It was unnecessary to remove the mucosa over the last point mentioned, as it was cut away in the resection. By proceeding with the denudation from within outward, the veins of the recto-vaginal septum were cut through at a high point and secured with compression forceps, and the necessity of repeatedly cutting the same vessels in the process of repairing the wound was avoided. (3) Two fingers were placed upon the promontory of the rectocele, carried into the vagina and out through the anus, forcing the rectocele ahead of them, and in this way completely everting it through the anus. It was seized with a pair of forceps at the point where it protruded and was gradually drawn down, step by step, until the lax portions were secured and a feeling of tenseness was felt. If in drawing the anterior rectal wall down the normal parts of the rectum did not come as low as the levator ani, the rectum should be liberated by dissecting it from the vagina, which would permit of further descent and allow all of the overstretched tissues to project beyond the anus. (4) A light pair of compression forceps is then placed upon the neck of the rectocele just external to the anus for the purpose of holding it in position. (5) Two sutures, preferably medium-sized kangaroo tendon, were passed through the unruptured portion of the perineum close to the sphincter ani muscle after the manner Emmet inserts his tension sutures in perineorrhaphy. These two sutures in passing across from side to side should take up the prolapsed portion of the anterior wall of the rectum. When tied, they closely approximated and anchored sound or healthy rectum to the levator ani muscle and rectal vessels in the deep pelvic fascia. (6) The vaginal side of the wound was completed by

doing perineorrhaphy. The protruding rectocele was amputated about three quarters to an inch external to the clamp, and its edges closely sutured with continuous suture of catgut. The case was treated then as an ordinary perineorrhaphy, except that a wet soft dressing was placed over the protruding stump. The stump retracted within the anus in a week's time, and took care of itself.

The author reported five cases, in which he did this operation, with very satisfactory results.

STARVATION AND LOCKED BOWELS FOR FROM TEN DAYS TO TWO WEEKS.

Dr. Howard A. Kelly, of Baltimore, Md., offered for a more extended trial in other fields as well a method of "after-treatment" which he had used in some fifteen cases, for the most part in complete tears of the recto-vaginal septum. The treatment consisted in two parts; first, a very limited diet for from ten to fifteen days; and, second, the locking up of the bowels during this period.

The food was limited to albumin and water, giving nothing the day following operation, and but 1 dr. every three hours in the second day, and increasing this a dram each day until the patient was taking 4 dr. every three hours. In this way the patient was fed in all in a period of ten days not quite three pints of albumin and absolutely no other food. One patient was continued for fifteen days on this diet and without an evacuation. At least two very frail patients had been treated in this way. When the evacuation took place, 2 dr. of licorice powder were given and in some cases an oil enema, and the passage was secured with the patient lying on her side so as to avoid any straining. In no case were there any scybala, or was there any difficulty with the evacuations.

Dr. Kelly thought this starvation plan of treatment might have a wider range of utility in treating dyspepsias and cases of hysteria, as well as in all kinds of plastic operations on the intestinal tract.

SURGICAL TREATMENT OF CANCER OF THE HEAD AND NECK, WITH A SUMMARY OF A HUNDRED AND TWENTY-EIGHT OPERATIONS PERFORMED UPON A HUNDRED AND TEN CASES.

Dr. GEORGE W. CHASE, of Cleveland, Ohio, in a paper on this subject, presented general conclusions to the effect that since the head and neck present an exposed field, cancer here, unlike that of the stomach, the intestines or even the breast, might be recognized at its very beginning; that every case was at some time curable by complete excision; that the field of regional metastasis was exceptionally accessible; that cancer rarely penetrated beyond the extraordinary lymphatic collar of the neck, that the growth tended to remain here localized, and that by freely utilizing all the modern resources of surgery, and by freely utilizing all the modern resources of surgery, by applying the same comprehensive block dissection, as in the radical operation for breast cancer, the final outcome in the surgical treatment of cancer of the head and neck should be not only as good, but even better than that of almost any other portion of the body.

WANDERING OR ADHERENT RETROPERITONEAL FIBROID TUMORS OF UTERINE ORIGIN.

Dr. I. S. STONE, of Washington, D. C., stated that these tumors must reach the space behind the peritoneum by way of the broad ligament. This route was the only one open and was necessarily followed by every fibroid which escaped into any part of the retroperitoneal space, however remote. After a fibroid

became well separated from the uterus, it usually remained in the broad ligament indefinitely, and would always do so unless other tumors developed in the uterus and were forced to follow directly in the same channel as the one preceding. It would be observed that single tumors were generally found in the broad ligament and the development of others must occur before we could have the variety we were studying. Many subperitoneal tumors were seen and few indeed had been noticed where the tumor had lost all connection with the uterus. Such growths could not become parasitic, and receive their nutrition from some other source, as did the intraperitoneal wandering or parasitic variety. He had no experience with a single wandering tumor behind the peritoneum which had entirely lost its uterine connections, and believed such development an impossibility for the reason mentioned above that a *vis a tergo* must exist. The movement of these tumors was, therefore, directly opposite to that of the intraperitoneal variety, for the latter must have either movable organs to assist in their progress, or else traction, a result of adhesive contact, must aid in the lifting or elevation of them upward in the abdominal cavity.

Dr. Stone reported two cases illustrating the variety he described in his paper. Both of these had grown to very large proportions. In the first, the largest tumor was very high in the abdomen, and was entirely separate from all former uterine connection including its blood supply. The presence of a large wedge-shaped middle portion was sufficient proof of the mode of development. It had forced other growths both upwards and downwards, acting as a wedge between the two. In the second case the central portion of the specimen was made up of many small tumors which had appeared to force the larger growths in opposite directions, as in the first one. The largest growth was highest, and was completely separated from the uterus and the tumors below, except by a small amount of connective tissue, and its anterior peritoneal cover. The pelvic tumors in both of these cases were firmly impacted, and in the second case it was impossible to release the specimen without injury to deep and unseen vessels which resulted in fatal hemorrhage. The first patient made a fairly satisfactory recovery, and was now able to attend to her duties as housekeeper.

(To be continued.)

Recent Literature.

1. *Textbook on Modern Maternal Medicine and Therapeutics.* By A. A. SIMMONS, A.M., M.D., Lecturer on Physical Diagnosis, University of Pennsylvania; Professor of Pathology, Woman's Medical College of Philadelphia. Fourth edition revised. Octavo of 670 pages. Philadelphia and London: W. B. Saunders Co., 1905.

The book is well written, well arranged and well indexed and conforms to the new (1905) Pharmacopoeia. The greater part of the volume is devoted to maternal medicine about one sixth to applied therapeutics. New articles have been added on scurvy, erythema, the menstrual and rubra with considerable new matter in the section on radiotherapy.

The work has something to offer to all of reference in the absence of reference to the various authors quoted in the text.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, MARCH 22, 1906.

A Journal of Medicine, Surgery and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 707 Paddock Building, 101 Tremont Street, Boston.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the undersigned.

Remittance should be made by money order, draft or registered letter, payable to

THE OLD CORNER BOOK STORE (Incorporated),
27 AND 29 BROMFIELD STREET, BOSTON, MASS.

THE PROGNOSIS IN EPILEPSY.

It is clear that our ultimate knowledge of the treatment of epilepsy must come from the study of a large number of patients observed under the most favorable conditions. This opportunity is being more and more offered year by year by the development of colonies and by the lapse of time which permits of the increasingly accurate observation of results. We look, therefore, each year with interest to the reports of the established colonies for the treatment of the disease and are rarely disappointed in finding experience or suggestions of value therein.

We have before us the annual report of the Craig Colony, a considerable portion of which is taken up with the report of the medical superintendent, Dr. William P. Spratling. For some years Dr. Spratling has taken an optimistic view regarding the treatment of epilepsy, and this, his latest report, proves confirmatory of ideas which he has previously expressed. He points out the desirability of earlier admissions if the best results are to be obtained. But twenty-five of the 1887 patients, hitherto admitted to the colony, had suffered from epilepsy less than a year at the time of admission. In fact, the largest number admitted had had the disease for many years and, therefore, could not be regarded as hopeful subjects for treatment. This is the more unfortunate inasmuch as epilepsy is essentially a disease of early life. The interesting statement is made that epilepsy is more common between birth and the fifth year than at any other period, and the next most common period is between the

tenth and the fifteenth year. In spite of the gross similarity between epileptics, Dr. Spratling insists on a close study of the individual as a prerequisite to success in treatment. It is an erroneous idea to suppose that the individual element is neglected in colony treatment in spite of the large number of patients under supervision.

Dr. Spratling speaks confidently of the curability of epilepsy. The statement is made that in from five to ten per cent. of the chronic cases at the colony a complete cure is effected. In other cases the seizures may be indefinitely arrested if the patients will live rigorously and in the prescribed manner. Freedom from epilepsy is held to be often merely a matter of right living. This freedom, however, cannot be secured in many cases by residence away from the colony. One patient is reported, who, after an immunity of twelve months from seizures and who in another twelve months would have been discharged cured, on a vacation of a month at home had five attacks in twenty days. The small things, according to Dr. Spratling, count for much, and it is Dr. Spratling's conviction that when epilepsy comes to be as rationally treated as tuberculosis is growing to be the percentage of cures will be from twenty-five to thirty per cent. or more. While admitting that Dr. Spratling has every reason to speak with authority in this matter, we are inclined to think that a more exact definition of what is meant by a cure is desirable. Certainly, immunity from attacks for two years, while at the colony, should not be regarded as a cure, if the attacks forthwith recur on return to ordinary life. The opinion frequently expressed of late by Dr. Spratling that the bromides have been used too much in epilepsy is reiterated. Approximately one half the cases at Sonyea are treated without the drug, and a larger dose than 20 gr. of the bromide of potash three times a day is seldom necessary.

Dr. Spratling's hopefulness is gratifying. We do not for a moment suppose that he speaks unadvisedly, and the whole tenor of succeeding reports goes to impress the fact that simplicity of life, a minimum drug treatment, and the avoidance of small sources of irritation, together with the study of the entire individual, are the essentials to success in treatment. That these conditions can be obtained better in colony life than in the individual home is self-evident. No doubt these hospitals, as many others, will grow more popular as time passes and their usefulness is increasingly demonstrated.

MEDICAL INSPECTION IN THE MASSACHUSETTS PUBLIC SCHOOLS.

A BILL now before the Massachusetts legislature, looking to the protection of the health of children in the public schools, should receive universal support. The committee having this bill in charge, under the chairmanship of Dr R. C. Cabot, is composed of a number of men and women who have the best interests of the Massachusetts schools at heart. The essential provisions of the bill are to provide prompt medical inspection of all children in the public schools who show signs of being in ill health and of those returning to school after absence, together with the exclusion of those having serious infectious disease, and systematic notification of parents. It also provides for an annual inspection of the children with a view to discovering defects in the special senses which are often a hindrance to the school work, both from the standpoint of teacher and pupil. Governor Guild and Dr H. P. Walcott have both indorsed the bill, as in fact it must be indorsed by all who take a broad view of the problems of secondary education.

The prompt detection of acute disease is manifestly of the greatest importance in the preservation of the public health. The ease with which contagion may be spread through school children is too manifest to require argument or reiteration. A case is reported which points a very distinct moral, of a boy in a New York school who passed round among his fellow scholars pieces of his skin; he had just recovered from scarlet fever. The matter of the detection of physical defects is somewhat more subtle but easy of accomplishment if the right machinery be brought to bear. It has been shown that approximately 25% of school children need glasses in order to do their work properly, and that about 5% are sufficiently defective in hearing to interfere with their school work. Teachers, unless specially trained, are unlikely to detect these defects, to the manifest detriment of the child. Punishment is not infrequently meted out to such defectives and they are placed in the category of the mentally inferior wholly from a failure to recognize the existing conditions. Truancy it is maintained frequently results from undetected physical defect although usually otherwise interpreted. In a plea for the passage of the bill the Massachusetts Civic League makes the following pertinent statements:

Our law obliges every child to go to school. Ought it not also to provide that when he gets there he shall not be liable to such injuries as

these? There can be no doubt as to the right to make such inspection. If it is the function of the school to teach the child to read, it may surely also ascertain whether he can see the letters. If it is its function to give him oral instruction, it must have the right to find out whether he can hear.

The cost of instituting the necessary reforms would be trifling in view of the advantages to be gained. It is essentially a campaign of education to instruct the teachers in the importance of recognizing signs of approaching illness or evidences of physical defect and to provide competent persons to verify or not, as the case may be, the suspicions of the teachers. It is evident that a comparatively simple system, carefully carried out in its details, would prevent much unnecessary suffering and would tend toward the best development of the pupils in the accomplishment of their preliminary education. Public opinion will undoubtedly support the bill and we have no doubt that the arguments in its favor will prove conclusive in the minds of the legislators.

MEDICAL INSPECTION OF PUBLIC SCHOOLS IN NEW YORK.

HEALTH COMMISSIONER DARLINGTON contributes an article on "The System of Medical School Inspection in the City of New York" to the annual report of the superintendent of the public schools, which has just been issued.

Boston was the first municipality in this country to introduce medical inspection in the public schools (1891). The system has been adopted in some fifteen of the Massachusetts cities and towns, and is being taken up in other states and cities. It has been carried further in Europe, especially in France and Prussia than it has in America. Mexico has a good system.

Dr. Darlington is, however, justified in claiming that although New York was not the first city to undertake medical inspection of school children, it has to-day the most comprehensive and highly developed system of any city on this continent and perhaps in the world, and he gives a sketch of the progress made in this department. In 1897 one hundred and fifty physicians were appointed medical inspectors, and each assigned to the supervision of from three to five schools. Each morning the inspector examines all children referred to him as possible sources of contagion. In June, 1902, six oculists were appointed to make special examinations of the children's eyes, with particular reference to trachoma. Beginning with September, 1902, in

addition to the daily morning inspections mentioned, each class room was visited once a week by the inspector. As a result of this inspection in the class rooms, 10,567 children were excluded from school during the first week of the service. In December, 1902, with a view to limit the duration of the periods of exclusion as far as consistent with the control of the source of contagion, a corps of school nurses, with a supervising nurse, was appointed. Each nurse visits the schools to which she is assigned every morning, and attends at its home each excluded child. The child is furnished with a diagnosis card, and as soon as the danger of infection has been eliminated the nurse returns the child to school, where an examination is again made by the medical inspector. Of course, the more serious cases receive treatment by physicians, in addition to the care of the nurse. In this way the child loses only a minimum of time from the class room, and statistics show that 98% of the excluded children are almost immediately enabled to resume their school attendance without exposing other children to the risk of contagion. Since March, 1905, the routine class room inspection has been made by the medical inspector only once a month. The nurse makes the weekly inspection, and refers all suspected cases to the inspector, who makes the diagnosis. A supplementary feature of the work is that each day the medical inspectors obtain from the school principals the names of all children who have been absent for three days or more without assigned cause. These children are visited in their homes, and in this way a large number of unreported cases of contagious disease have been discovered.

MEDICAL NOTES.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION. — The British Medical Association will hold its annual meeting this year at Toronto from Aug. 21 to Aug. 25. The president is George C. Franklin, F.R.C.S., of Leicester, England. The president-elect is R. A. Reeve, M.D., LL.D., of Toronto.

HONORS TO DR. G. L. SIMMONS. — The Sacramento Society for Medical Improvement on March 13 gave a dinner in commemoration of the fiftieth anniversary of Dr. G. L. Simmons's graduation in medicine. Many physicians were present, not only from Sacramento, but from neighboring cities, and numerous telegrams of regret were received from physicians unable to be present.

A loving cup was presented to Dr. Simmons, and several appreciative speeches were made commemorative of his work both as a man and a physician. Dr. Simmons was a graduate of the Harvard Medical School in the class of 1856, ex-President of the California State Medical Society and founder of the Sacramento Society for Medical Improvement, a worthy offspring of the Boston Society of the same name, which has been long influential in the medical history of this city.

BOSTON AND NEW ENGLAND.

ACUTE INFECTIOUS DISEASES IN BOSTON. — For the week ending at noon, March 21, 1906, there were reported to the Board of Health of Boston the following cases of acute infectious diseases: Diphtheria 35, scarlatina 28, typhoid fever 6, measles 185, tuberculosis 46, smallpox 0.

The death-rate of the reported deaths for the week ending March 21, 1906, was 22.78.

BOSTON MORTALITY STATISTICS. — The total number of deaths reported to the Board of Health for the week ending Saturday, March 17, 1906, was 224, against 233 the corresponding week of last year, showing a decrease of 9 deaths and making the death-rate for the week 19.63. Of this number 98 were males and 126 were females; 219 were white and 5 colored; 138 were born in the United States, 81 in foreign countries and 5 unknown; 46 were of American parentage, 154 of foreign parentage and 24 unknown. The number of cases and deaths from infectious diseases reported this week is as follows: Diphtheria, 35 cases and 2 deaths; scarlatina, 34 cases, no deaths; typhoid fever, 6 cases and no deaths; measles, 204 cases and 4 deaths; tuberculosis, 78 cases and 26 deaths; smallpox, no cases and no deaths. The deaths from pneumonia were 31, whooping cough 0, heart disease 20, bronchitis 4, and marasmus 4. There were 14 deaths from violent causes. The number of children who died under one year was 37; the number under five years, 59. The number of persons who died over sixty years of age was 56. The deaths in public institutions were 67.

There were 2 deaths and 1 case of cerebro-spinal meningitis reported during the week.

ANTIVIVISECTIONISTS HAVE LEAVE TO WITHDRAW. — The Committee on Probate and Chancery in the Massachusetts Senate have reported leave to withdraw on the petition of Elizabeth Stuart Phelps Ward and others to prohibit vivisection. The hearings this year were less animated than heretofore.

POISONING BY WOOD ALCOHOL.—Medical Examiner William D. Swan has reported to the Cambridge (Mass.) Board of Health that the recent sudden death of a female student at Radcliffe was due to poisoning by wood alcohol. This death was at first attributed to "overwork."

BILLS BEFORE THE LEGISLATURE.—A bill introduced by Frederick W. Peabody directed especially against Christian Science has been reported by the committee in charge leave to withdraw. The committee reported leave to withdraw on a bill providing for a state board of registration in osteopathy. Several other bills relating to the practice of medicine were also given leave to withdraw.

MIDDLESEX EAST DISTRICT MEDICAL SOCIETY.—The Middlesex East District Medical Society held its regular monthly meeting at the American House, Boston, Wednesday evening, March 14. Dr. Silas H. Parks, president, in the chair. The paper of the evening was by Dr. E. S. Jack. In accordance with the vote of a previous meeting the president appointed the following a committee on the prevention and control of tuberculosis: Dr. George F. Dow, Reading; Dr. Richard Dutton, Wakefield; Dr. Francis E. Park, Stoneham; Dr. Ralph R. Stratton, Melrose; Dr. William H. Keeler, Woburn; Dr. Harold Gale, Winchester; C. W. Harlow, M.D., secretary.

BOLLARD PROFESSORSHIP OF NEUROPATHOLOGY.—The text of the deed of gift of a newly established chair in neuropathology in Harvard University is as follows: "In memory of William Story Bollard, East India merchant of Boston, who was for twenty-three years a trustee of the McLean Asylum, to record his unflinching interest in the relief of sufferers from nervous or mental disease and his belief in benefits from future scientific research, I, Louisa Norton Bollard, his widow, give for myself and our children the sum of fifty thousand dollars to the president and fellows of Harvard College for the endowment of a professorship in neuropathology to be entitled the Bollard Professorship of Neuropathology. This professorship shall embrace study, research, investigation and teaching in relation to disease of the nervous system, whether functional or organic, and shall include not only the affection ordinarily classed under neurology but all mental diseases and disturbances, both those classed under psychiatry and any others that may exist. The methods and detail of work

under this professorship are not restricted. It should include any form of research and investigation which may lead to the increase of knowledge of nervous or mental disease. It comprises the comparative study of these diseases in animals and other living forms."

NEW YORK.

ADDITION TO ST. JOHN'S HOSPITAL.—The Sisters of St. Joseph, who have the direction of St. John's Hospital in Long Island City, have filed plans for an addition to the building to cost \$200,000. The new wing will face Jackson Avenue and will be larger than the present building, which has a capacity of seventy beds.

ABUSES IN USE OF PATENT MEDICINE.

During the present season, as a result of public sentiment on the abuses attending the use of patent medicines, there has been organized the "New York State General Committee for Safeguarding the Sale of Narcotics." William A. Jenner is chairman; Wm. T. Wardwell, first vice-chairman, and Dr. A. Jacobi, second vice-chairman, and among the members of the Executive Committee are Drs. W. Gilman Thompson, E. Eliot Harris and Wisner R. Townsend. Under the direction of the committee a bill was drafted by such men as Bishop Doane of Albany, Bishop Greer of New York, ex-Mayor Low, Prof. Charles F. Chandler, Prof. Charles Baskerville, and Dr. Ernst J. Lederle. It is entitled "An act to amend the public health law by providing for the proper labeling of proprietary and other medicinal preparations containing alcohol or narcotic or other powerful drugs, and for the inspection, analysis and regulation of the manufacture and sale of the same." This bill was duly introduced in both branches of the legislature, and on March 14 a hearing was given it before the Senate Committee on Public Health. Among those who spoke in favor of its passage were Dr. H. F. K. Shaw of Albany and Drs. Edward C. Janeway and Albert I. Weston of New York. The principal opposition to the bill, it is stated, comes from the Proprietary Medicine Association of America.

Miscellany.

THE BORDER LINE IN MEDICINE AND SURGERY.

E. C. JANEWAY states that the rule which should be formulated in a physician's mind is that no operation should be performed without a cer-
